A TREATISE ON SURGERY. By American Authors for Students and Practitioners of Surgery and Medicine. Edited by Roswell Park, A.M., M.D., Professor of the Principles and Practice of Surgery and of Clinical Surgery in the Medical Department of the University of Buffalo. Third Edition, Enlarged and Thoroughly Revised. With 692 Engravings and 64 Full-page Plates in Colors and Monochrome. Cloth. Pp. 1408. Price, $7.00 net. New York and Philadelphia: Lea Brothers & Co. 1901.

A MANUAL OF VOLUMETRIC ANALYSIS. Treating on the subjects of Indicators, Test-Papers, Alkalimetry, Acidimetry, Analysis by Oxidation and Reduction, Iodometry, Assay Processes for Drugs with the Titrimetric Estimation of Alkaloids, Estimation of Phenol, Sugar: Tables of Atomic and Molecular Weights. By Virgil Coblentz, Ph.D., Pharm.D., F.C.S., Professor of Chemistry in the New York College of Pharmacy. Illustrated. Cloth. Pp. 181. Price, $1.25. Philadelphia: P. Blakiston's Son & Co. 1901.

TYPHOID AND TYPHUS FEVERS. American Edition of Nothnagel's Encyclopedia. By Dr. H. Curschmann, of Leipzig. Edited, with additions, by William Osler, M.D., Professor of the Principles and Practice of Medicine, Johns Hopkins University. Handsome octavo of 646 pages, illustrated, including a number of valuable temperance charts and two full-page colored plates. Cloth, $5.00 net. Philadelphia and London: W. B. Saunders & Co., 1901.

A REFERENCE HANDBOOK OF THE MEDICAL SCIENCES, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition, Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume III. Illustrated by Chromolithographs and 676 Half-tone and Wood Engravings. Cloth. Pp. 861. Price, $7.00 per volume. New York: William Wood & Co. 1901.

A TEXT-BOOK OF PHARMACOLOGY and Some Allied Sciences. (Therapeutics, Materia Medica, Pharmacy, Prescription-Writing, Toxicology, etc.) By Torald Sollmann, M.D., Assistant Professor of Pharmacology and Materia Medica in the Medical Department of Western Reserve University, Cleveland, Ohio. Illustrated. Cloth. Pp. 894. Price, $3.75 net. Philadelphia and London; W. B. Saunders & Co. 1901.

A TEXT-BOOK OF MEDICINE. Begun by the late Charles Hilton Fagge, M.D., F.R.C.P., Sometime Physician to Guy's Hospital. Completed after his death and since revised or re-written by Philip Henry Pye-Smith, M.D., F.R.S., Fellow of the Royal College of Physicians. Fourth Edition. In Two Volumes. Vol. I. Cloth. Pp. 1123. Price, $6.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

AN AMERICAN TEXT-BOOK OF PATHOLOGY. Edited by Ludvig Hektoen, M.D., Professor of Pathology, Rush Medical College, Chicago; and David Riesman, M.D., Professor of Clinical Medicine, Philadelphia Polyclinic. Handsome imperial octavo of 1245 pages, 443 illustrations, 66 of them in colors. Cloth, Price, $7.50. Philadelphia and London: W. B. Saunders & Co., 1901.

"FIRST-AID" to the Injured and Sick. An Ambulance Handbook. By F. J. Warwick, B.A., M.B., Cantab., M.R.C.S., L.S.A., Associate of King's College, London, and A. C. Tunstall, M.D., F.R.C.S. Ed., Surgeon-Captain Commanding the East London Volunteer Brigade Bearer Company. Cloth. Pp. 232. Price, $1.00. Philadelphia and London: W. B. Saunders & Co. 1901.

THE SURGICAL TREATMENT OF DISFIGUREMENTS AND DEFORMITIES OF THE FACE. By John B. Roberts, A.M., M.D., Professor of Surgery in the Philadelphia Polyclinic, Second Edition, with a Chapter on the Reconstruction of Syphilitic Noses. Illustrated with 62 Figures. Cloth. Pp. 72. Philadelphia: The Philadelphia Medical Publishing Co. 1901.

"OUR ACCURSED SPELLING." What to Do with It. Max Mueller, LL.D.; Wm. D. Whitney, LL.D., L.H.D.; S. S. Haldemann, LL.D., L.H.D.; Francis L. March, LL.D., L.H.D.; Wm. T. Harris, LL.D.; Hon. Joseph Medill, and T. R. Lounsbury, LL.D. Paper. Pp. 142. Price, $0.25. Edited and Published by E. O. Vaille, Oak Park, Chicago.

A LABORATORY HAND-BOOK OF URINE ANALYSIS AND PHYSIOLOGICAL CHEMISTRY. By Charles G. L. Wolf, B.A., M.D., Instructor in Physiological Chemistry, Cornell University Medical College, New York. Illustrated. Cloth. Pp. 203. Price, $1.25. Philadelphia and London: W. B. Saunders & Co. 1901.

TRANSACTIONS OF THE MISSISSIPPI STATE MEDICAL ASSOCIATION. Thirty-fourth Annual Session, held at Jackson, April 8, 9 and 10, 1901. With the Roll of Members and Reports on Medical Topics. Cloth. Pp. 264. Published by the Association. Oxford, Miss.: Globe Printing Office. 1901.

STUDIES OF THE INTERNAL ANATOMY OF THE FACE. By M. H. Cryer, M.D., D.D.S., Professor of Oral Surgery, Department of Dentistry of the University of Pennsylvania. Cloth. Pp. 176. Price, $1.50 net. Philadelphia: The S. S. White Dental Mfg. Co. 1901.

TWENTY-EIGHTH ANNUAL REPORT OF THE SECRETARY OF THE STATE BOARD OF HEALTH OF THE STATE OF MICHIGAN for the Fiscal Year Ending June 30, 1900. Cloth. Pp. 272. Lansing, Mich.: Wynkoop, Hallenbeck, Crawford Co. 1901.

INDEX-CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, U. S. A. Authors and Subjects. Second Series. Vol. VI. G—Hernette. Cloth. Pp. 1051. Washington: Government Printing Office. 1901.

TRANSACTIONS OF THE MICHIGAN STATE MEDICAL SOCIETY for the Year 1901. Volume XXV. Cloth. Pp. 575. Detroit: Published by the Society. 1901.

TRANSACTIONS OF THE RHODE ISLAND MEDICAL SOCIETY, 1900. Vol. VI, Part II. Paper. Pp. 277. Providence: Snow & Farnham. 1901.

TRANSACTIONS OF THE MAINE MEDICAL ASSOCIATION, 1901. Vol. XIV. Part I. Paper. Pp. 222. Portland: Stephen Berry. 1901.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Nov. 14 to 20, 1901, inclusive:

Robert A. Anderson, captain and asst.-surgeon, Vols., having tendered his resignation, is honorably discharged from the service of the United States.

Bailey K. Ashford, lieutenant and asst.-surgeon, U. S. A., from Fort Slocum, N. Y., to Havana, Cuba, for assignment in the Department of Cuba.

David Baker, lieutenant and asst.-surgeon, U. S. A., is relieved from duty on the transport *Meade*, and from the Division of the Philippines, to proceed to Fort Slocum, N. Y., for duty at that post.

George E. Bushnell, major and surgeon, U. S. A., member of a board at Denver, Colo., to determine the fitness of certain persons for appointment in the U. S. Army.

Charles B. Byrne, lieut.-col., deputy surgeon-general, member of a board in St. Paul, Minn., to determine the fitness of officers of the Army for promotion.

Walter C. Childester, lieutenant and asst.-surgeon, Vols., honorably discharged as a captain and asst.-surgeon, Vols., of date Nov. 1, 1901.

Harvey A. Eberle, captain and asst.-surgeon, Vols., from duty at Fort Totten, N. Y., to accompany troops to be sent to the Philippine Islands on the transport *Crook*, to sail from New York City, N. Y., about December 1, 1901.

William J. Enders, contract surgeon, now at Philadelphia, Pa., to proceed to Fort Delaware, Del., for post duty.

Clyde S. Ford, lieutenant and asst.-surgeon, U. S. A., having reported to the Surgeon-General, as required by previous orders, is assigned to duty at the General Hospital, Washington Barracks, D. C.

John D. Hall, lieut.-col., deputy surgeon-general, leave of absence for one month granted.

Luther S. Harvey, captain and asst.-surgeon, Vols., leave of absence for one month granted, with permission to apply for an extension of twenty-five days.

Frank R. Keefer, captain and asst.-surgeon, U. S. A., member of an examining board at Fort Monroe, Va., vice Lieut.-Col. Robert M. O'Reilly, deputy surgeon-general, relieved.

John S. Kulp, captain and asst.-surgeon, U. S. A., from New York City, N. Y., to San Francisco, Cal., for duty as post surgeon at that place.

William C. LeCompte, contract surgeon, from Fort Niagara, N. Y., to San Francisco, Cal., for duty with troops en route to Manila, P. I., for subsequent assignment in the Division of the Philippines.

Robert W. Morgan, contract dental surgeon, leave of absence on certificates of sickness extended two months.

Edward R. Morris, major and surgeon, U. S. A., relieved from duty in the Department of the Lakes, to proceed to San Francisco, Cal., for duty at the model camp to be established on Angel Island, San Francisco, Cal.

Edward B. Moseley, major and surgeon, U. S. A., member of a board at Denver, Colo., to determine the fitness of certain persons for appointment in the U. S. A.

Elbert E. Persons, lieutenant and asst.-surgeon, U. S. A., member of a board in St. Paul, Minn., to determine the fitness of officers of the Army for promotion.

Henry I. Raymond, major and surgeon, U. S. A., previous orders amended so as to direct him to report to the commanding officer of troops to be sent to the Philippine Islands on the transport *Buford*, to sail from New York City, on or about Jan. 15, 1902, and on arrival at Manila, P. I., to report for assignment in the Division of the Philippines.

Ira A. Shimer, lieutenant and asst.-surgeon, U. S. A., from duty in the Department of Cuba, to post duty at Fort Niagara, N. Y.

Henry D. Snyder, captain and asst.-surgeon, U. S. A., from duty in the Division of the Philippines to New York City, to enter upon duty as attending surgeon and examiner of recruits in that city.

Benjamin L. Ten Eyck, captain and asst.-surgeon, U. S. A., now on sick leave, is relieved from duty in the Department of the East and will proceed to Fort Wayne, Mich., for duty.

William H. Wilson, captain and asst.-surgeon, U. S. A., is relieved from duty in the Department of California to report for transportation to the Philippine Islands for service in the Division of the Philippines.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ended Nov. 23, 1901:

Surgeon L. L. von Wedekind, ordered to the *Cincinnati*, December 2.

Medical Inspector L. G. Heneberger, commissioned medical inspector from Oct. 29, 1901.

P. A. Surgeon H. H. Haas, commissioned P. A. surgeon from Dec. 28, 1900.

Surgeon H. L. Law, retired, additional duty as examining surgeon at Marine-Recruiting Station, Buffalo, N. Y.

P. A. Surgeon H. D. Wilson, detached from Naval Hospital, Norfolk, Va., ordered home and granted three months' sick leave.

The leave granted Surgeon John W. Ross, U. S. Navy, retired, is extended one month. From Circular Letter, Department of Cuba, dated November 11.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the fourteen days ended November 14, 1901:

Surgeon A. H. Glennan, granted leave of absence for one month from November 16.

Surgeon L. L. Williams, granted leave of absence for three days.

Surgeon G. N. Magruder, granted leave of absence for fifteen days from November 15.

Asst.-Surgeon John McMullen, granted four days' extension of leave of absence, Nov. 2, 1901. Upon being relieved by Asst.-Surgeon C. C. Pierce, to proceed to Baltimore, Md., and report to the medical officer in command for duty and assignment to quarters.

Asst.-Surgeon H. C. Russell, granted leave of absence for two days.

Asst.-Surgeon Dunlop Moore, granted leave of absence for six days.

Asst.-Surgeon C. C. Pierce, relieved from duty at Key West, Fla., and directed to proceed to Mullet Key Quarantine and assume command of the service, relieving Asst.-Surgeon John McMullen.

Hospital Steward G. H. Brock, upon being relieved by Hospital Steward Edward Rogers, to proceed to Detroit, Mich., and report to the medical officer in command for duty and assignment to quarters.

Hospital Steward Edward Rogers, relieved from duty at Detroit, Mich., and directed to proceed to Cincinnati, Ohio, and report to medical officer in command for duty and assignment to quarters, relieving Hospital Steward G. H. Brock.

A. A. Surgeon Jay Tuttle, department letter of Oct. 4, 1901, granting A. A. Surgeon Tuttle leave of absence for thirty days, revoked.

Hospital Steward and Chemist Henry Gahn, granted leave of absence for twenty days from November 11.

Hospital Steward G. H. Brock, granted leave of absence for four days from November 12.

Hospital Steward S. W. Richardson, relieved from duty in connection with the Pan-American Exposition, and directed to report to medical officer in command at Buffalo, N. Y., for temporary duty.

Hospital Steward E. B. Scott, relieved from duty at Washington, D. C., and directed to proceed to Baltimore, Md., and report to medical officer in command for duty and assignment to quarters, relieving Hospital Steward F. A. Southard.

Hospital Steward H. R. Mason, upon expiration of leave of absence, to report to medical officer in command at San Francisco, Cal., for duty and assignment to quarters.

Hospital Steward F. A. Southard, upon being relieved by Hospital Steward E. B. Scott, to proceed to New York City, and report to medical officer in command for duty and assignment to quarters.

Hospital Steward M. H. Waters, relieved from duty at Washington, D. C., and directed to proceed to Boston, Mass., and report to medical officer in command for duty and assignment to quarters.

P. A. Surgeon M. J. Rosenau, detailed to represent the service at meeting of the New York State Association of Railroad Surgeons at New York City, November 16 and 17.

P. A. Surgeon H. S. Cumming, granted extension of leave of absence on account of sickness for thirty days from October 30.

P. A. Surgeon J. B. Greene, granted leave of absence for twenty-one days from November 23.

Asst.-Surgeon H. G. Russell, bureau letter of November 2, granting Asst.-Surgeon Russell leave of absence for two days, amended so that said leave shall be for seven days.

Asst.-Surgeon F. J. Thornbury, to proceed to Port Townsend, Wash., and report to medical officer in command for temporary duty.

Asst.-Surgeon Dunlop Moore, to proceed to Honolulu, H. I., and report to medical officer in command for duty.

Asst.-Surgeon J. M. Holt, relieved from duty at Chicago, Ill., and temporary duty at Cairo, Ill., and directed to proceed to St. Louis, Mo., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon L. P. H. Bahrenburg, relieved from duty at Honolulu, H. I., and directed to proceed to Chicago, Ill., and report to medical officer in command for duty and assignment to quarters.

A. A. Surgeon V. B. Gregory, granted leave of absence for seven days from November 12.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Nov. 23, 1901:

SMALLPOX—UNITED STATES.

California: San Francisco, Nov. 3-10, 1 case.
Illinois: Chicago, Nov. 9-16, 1 case.
Indiana: Evansville, Nov. 9-16, 2 cases.
Kansas: Wichita, Nov. 9-16, 5 cases.
Kentucky: Lexington, Nov. 9-16, 2 cases.
Louisiana: New Orleans, Nov. 9-16, 4 cases, 1 death.
Massachusetts: Boston, Nov. 9-16, 28 cases, 3 deaths.
Michigan: Grand Rapids, Nov. 9-16, 1 case.
Nebraska: Omaha, Nov. 9-16, 4 cases.
New Jersey: Camden, Nov. 9-16, 1 case; Newark, Nov. 9-16, 18 cases, 1 death; Passaic, Nov. 9-16, 3 cases.
New York: New York, Oct. 9-16, 8 cases, 3 deaths.
Ohio: Cincinnati, Nov. 8-15, 1 case; Zanesville, Sept. 3-Oct. 3, 1 case.
Pennsylvania: Lebanon, Nov. 3-16, 6 cases; Norristown, Nov. 9-16, 16 cases; Philadelphia, Nov. 9-16, 50 cases, 12 deaths.
Rhode Island: Newport, Nov. 9-16, 2 cases.
Vermont: Burlington, Nov. 9-16, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Oct. 26-Nov. 2, 2 cases.
Belgium: Ghent, Oct. 19-Nov. 2, 7 deaths.
Brazil: Rio de Janeiro, Oct. 12-19, 50 deaths.
Canada: Quebec, Nov. 9-16, 41 cases; St. John, Nov. 9-16, 4 cases.
Colombia: Cartagena, Oct. 19-Nov. 2, 7 cases, 7 deaths; Panama, Oct. 29-Nov. 5, 100 cases.
France: Paris, Oct. 19-Nov. 2, 9 deaths.
Great Britain: Glasgow, Nov. 1-8, 1 case; Liverpool, Oct. 19-26, 1 death; London, Oct. 26, Nov. 2, 464 cases, 14 deaths.
India: Madras, Oct. 12-18, 1 death.
Italy: Naples, Oct. 26-Nov. 2, 28 cases, 1 death.
Nova Scotia: Halifax, Nov. 9-16, 6 cases.
Russia: Moscow, Oct. 19-26, 2 cases, 2 deaths; Odessa, Oct. 26-Nov. 2, 2 deaths; Warsaw, Oct. 12-19, 2 deaths.
Spain: Corunna, Oct. 26-Nov. 2, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, Oct. 13-20, 3 deaths.
Mexico: Vera Cruz, Nov. 2-9, 24 cases, 10 deaths.
West Indies: Curacao, Oct. 26-Nov. 2, 2 cases, 1 death.

CHOLERA.

India: Bombay, Oct. 18-22, 4 deaths; Karachi, Oct. 12-18, 60 deaths.
Straits Settlements: Singapore, Sept. 28-Oct. 5, 2 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Nov. 4, 1 case, 1 death.

PLAGUE—FOREIGN AND INSULAR.

Philippine Islands: Manila, Sept. 14, 3 cases.
Africa: Cape Colony, Oct. 12-19, 4 deaths.
Brazil: Rio de Janeiro, Oct. 13-20, 15 deaths.
China: Hongkong, Oct. 7, 3 cases, 2 deaths.
Great Britain: Glasgow, Nov. 8, 3 cases, 2 deaths; Liverpool, Oct. 19-26, 5 cases, 2 deaths.
India: Bombay, Oct. 15-22, 179 deaths; Karachi, Oct. 13-23, 23 cases, 15 deaths.
Mauritius: Oct. 24, 71 cases, 37 deaths.

Address.

THE SURGICAL TREATMENT OF BILIARY CALCULI, WITH SPECIAL REFERENCE TO HEPATOTOMY.

PRESIDENT'S ADDRESS, DELIVERED AT THE FOURTEENTH ANNUAL MEETING OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS, HELD AT CLEVELAND, SEPTEMBER 17, 18 AND 19, 1901.

W. E. B. DAVIS, M.D.

BIRMINGHAM, ALA.

INTRODUCTION.

For the distinguished honor conferred on me at our last meeting in my election to the Presidency of this Association, numbering among its members so many leaders in gynecology and abdominal surgery, I beg first of all to return my most profound thanks. The Association occupies a unique position among our national special societies. It has overcome difficulties and accomplished results scarcely equaled and not excelled by any other special organization in this country. Its foundation was a necessity, it being admitted even by the members of the American Gynecological Society that that society was not sufficiently representative. Dr. Marion Sims, who, in 1880, in his presidential address urged the increase of the limit of membership from 60 to 100, which was done in 1884, said: "It is not to be denied that there is a very large element of discontent among men who are our equals in everything, and who might be organized into a formidable rival national association. Dr. Theophilus Parvin in his address, in 1893, made this statement: "These words"—Dr. Sims'—"were prophetic, the prophecy is history and there is a formidable rival national association. The association numbers many able members and has done very creditable and useful work." It was after our Association was established and its success assured that the Gynecological Society began a general and active canvass for Fellows and increased its membership from 58 to 94. Its Fellows were able men—leaders as a rule—and as a society it gave prestige to American gynecology, but there were many of their peers who had not been encouraged to become members, and, on the contrary, a number of distinguished and able workers had been denied this privilege.

The following from the presidential address of Dr. Robert Battey, in 1888, testifies to the above: "In the past, America has been, in a sense, the home of gynecology. To-day no country can boast of so large a number of intelligent workers in this department of the healing art. In our vast country the number of medical practitioners who devote themselves exclusively to gynecology is quite large, whilst those who make it a leading pursuit are to be counted by thousands. Surely out of this army of gynecological specialists one hundred men can be found who might worthily occupy places as working Fellows in this Society. Why is it, then, our seats remain year by year scarcely more than half filled? When I say to you in all sincerity that if I myself were to-day outside, instead of inside the ranks, distrust would forever bar me from becoming an applicant at your doors except upon special invitation, I can but feel that I am verging toward the true explanation of our forty-two vacant chairs. Diligent workers in medical science are, with an occasional exception which but proves the rule, modest gentlemen, not at all inclined to push themselves where they are not wanted. It is this class of members which we especially desire, and it is this class, too, who are least likely to make application for the Fellowship without some advance on our part which would give probable assurance of welcome."

It was natural for some men who were invited to come into our Association to prefer the older and well-established organization, hallowed by the names of so many of our distinguished countrymen and also for a number of our members to go into that society. The great majority, however, preferred the new organization, projected on a broader plane, and would not yield to inducements to give it up, and, as a result, this Society has increased in number and influence, and no one can deny that it is a representative American Association of our foremost gynecologists and abdominal surgeons. Its thirteen volumes of transactions are in every way highly creditable to American gynecology. They are not excelled by the published work of any other American society and reflect the greatest credit upon our members and especially the ability of our scholarly secretary, to whom we owe so much for the present high position this organization occupies. He has been its sculptor, and in the language of our first president, Dr. Taylor, "Upon the obelisk of the Association, erected by the earnest work of its members, there will stand in imperishable letters the name of William Warren Potter." I wish that time would permit my mentioning the names of those noble, earnest workers who joined Drs. Potter and Vander Veer in projecting and establishing this great Association.

The Association's first president, who served a second term, closed his last address in these words: "The recent advancement in all departments of science and the wonderful practical application of newly acquired facts, disarm incredulity and we dare place no limit upon the

possible acquisitions of the near future. The Utopias of to-day may be the familiar dwelling-places of to-morrow; and, actuated by the noble sentiment which so characterizes our profession, of seeking the truth for the truth's sake, we may be sure of grand additions to our knowledge and skill, and I can utter no better benediction than the hope that this Association may bear its full share of making these acquisitions." To-day I am able to state with much pride that many of the mooted questions in abdominal and pelvic surgery have been made clearer by our Fellows and that they have added materially to our store of knowledge.

The need of specialism in the profession and of special societies for the promotion of the several specialties have been ably and most exhaustively treated by our foremost men. The national special societies have wielded a wonderful influence in the profession and have added greatly to our reputation abroad. Our medical literature has been enhanced in every way through them. They have been incentives to higher aims and better work in all departments. As individual societies they should be encouraged, but their union into a national congress or association is not conducive to the best interests of the American profession. The greatest and most influential organization of the United States should be the AMERICAN MEDICAL ASSOCIATION. Both the specialists and the general practitioners of this country should belong to that Association and take pride in their membership and exert their best energies in behalf of its meetings, as urged by our fellow, Dr. Wright. Many of our ablest men, as claimed by him, have been conspicuous by their absence. Failure to be an active contributor to the work of this national organization should be a justly deserved reflection on a prominent physician, whether he be a general practitioner or a specialist. Several years ago there was some reason for the want of interest in the organization, as there was too much politics and too little scientific work. However, for the past few years the scientific work of the Sections has been of a high order, and a great deal has been accomplished in the time allowed. With the adoption of the new organization providing for the House of Delegates to take charge of all business matters and questions of a judicial or personal nature, more time will be provided for scientific work, the Sections having as many sessions as provided for the meetings of our national special societies. The special societies, composed as they are of leaders in the several specialties, are under obligations to the American profession to assist in the better organization of these Sections. Many of the members of these societies are officers and active working members of the Sections of the American Medical Association and can accomplish this result. There must be one class of membership for the Section that can be held by only those who are recognized as teachers and leaders in order to make membership very desirable and sought after. I would suggest that this class be known as Fellows and that they pay, in addition to the annual dues of the Association, $5 annually for Section dues, which fund should be expended in the publication of the proceedings of the Section. The officers and authors of papers should come from the Fellows. All members would have the privilege of taking part in the discussions and thus an opportunity would be provided for the ordinary or Association members to show themselves worthy of a fellowship. Such an organization of the Sections with volumes of Transactions, publishing a list of the Fellows, would give stability and a permanency to the Section work that could scarcely be had in any other way. With the House of Delegates for the general association and the Roll of Fellows and Association Members for each of the Sections, we would become the most scientific and influential medical organization the world has ever known.

The American Association of Obstetricians and Gynecologists has it in its power to so organize the Section of Diseases of Women, and the members of this Section, I believe, could induce the leaders in the other Sections to adopt the plan outlined or something after that plan. It is not enough that we should succeed as specialists and that our special societies should succeed, but they should prove a source of strength to the entire profession which can be best subserved by strengthening the American Medical Association, making it not only a power in scientific work, but giving it the prestige which will enable scientific medicine to receive due recognition from our national government. If our Fellows accomplish as much, they will have rendered the medical profession an invaluable service.

I now come to the subject which I have selected for discussion:

THE SURGICAL TREATMENT OF BILIARY CALCULI, WITH SPECIAL REFERENCE TO HEPATOTOMY.

Biliary calculi being found in from 2 to 20 per cent. of autopsies, the frequency increasing with age, makes the subject one of vast importance. Cases are now quite properly studied according to the location of stones and the resultant pathologic conditions. In every case, if the diagnosis could be made, the stones should be removed, in view of the multiform changes they are capable of producing. Fortunately for the patient, in a large proportion no trouble or symptoms ever occur. Hence, the diagnosis during life could be made only by an abdominal section, as the *x*-ray is not capable of demonstrating their presence except in a very small per cent. of cases.

The correct surgical management of gall-bladder and cystic duct calculi was first planned and put into practice in 1878, by that surgical genius from Alabama, who did so much to advance gynecology—the immortal Marion Sims. There has been little improvement on his original operation. Bobbs, of Indiana, in 1867, opened a gall-bladder containing calculi, but it had become attached to the abdominal parieties and his operation was nothing more than the incision of a simple abscess, as has been conclusively shown by Joseph Eastman. Cholecystostomy, with the attachment of the walls of the gall-bladder to the peritoneum and deep fascia of the abdominal wound is ideal and attended by less than 1 per cent. mortality. Only a small per cent. of fistulæ will follow this technique, while 40 per cent. has been the result of attaching the gall-bladder to the skin.

Much has been claimed within the past five years for cholecystendysis, with or without drainage of the abdominal cavity. While this operation has something to commend it, being simple and obviating the disagreeable discharge of bile, for from three to four weeks, from a fistula, yet its field is limited when the etiology and pathology of cholelithiasis are given due consideration. Stagnation of bile with altered epithelium and infection from the typhoid or colon bacillus, as found in many cases, where there is no evidence of infection from the character of the fluid in the bladder, would contraindicate its closure. If stones should be found, where an examination of the gall-bladder is conducted through

the abdominal incision made for the relief of pelvic disease or other abdominal trouble, cholecystendysis might be performed with advantage. I would advise strongly against the operation as performed by Kelly. The first incision in the abdomen should be closed and the opening made as in the classic cholecystotomy. Cases in which calculi would be found by this method are not associated with inflammatory changes and are the ones that go through life without symptoms referable to the gall-bladder, being found at the autopsy or in the dissecting room.

Cholecystectomy—first recommended in 1882 by Langenbuch—is indicated in gangrene of the gall-bladder, multiple or perforating ulcers, stricture of cystic duct, phlegmonous cholecystitis, empyema with great danger to the walls of the viscus, and malignant disease. It should not be done as a rule in chronic cholecystitis, when the bladder is too small to attach to the abdominal wall, notwithstanding it is recommended by Robson and others. Drainage with tube and gauze is to be preferred. It should never be completed until the common duct has been thoroughly explored and found to be patent. In the majority of cases it is advisable to trim off the diseased portion of the bladder from the liver instead of removing the entire viscus, and drain with gauze. The mortality of this operation is from 3 to 25 per cent., according to the condition Being called for in serious inflammatory and malignant diseases makes its mortality larger than cholecystostomy.

On November 25, of last year, Hans Kehr[1] had performed 547 gallstone operations, with the following results: 204 conservative operations on the gall-bladder (cystostomies, cystotomies, cystendyses) with 4 deaths; 121 cystectomies, with 4 fatal cases, and 97 choledochotomies, with 6 deaths. The mortality was 47 per cent. in gallstone diseases complicated with carcinoma of the liver, of the gall bladder, of the choledochus or the pancreas, or if there existed diffuse purulent cholangitis, peritonitis or cirrhosis of the liver.

Since 1890 the surgery of the common duct has attracted wide attention. Schloth, in 343 cases of biliary calculi, found 2.6 per cent. in the duct. Fenger estimates that from 2.6 to 15 per cent. of cholelithiasis are choledochus cases. Mayo Robson thinks from a surgical standpoint 20 per cent. would not be too large an estimate, which corresponds with Kehr's experience. At the Indianapolis meeting of this Association, Dr. Joseph Eastman, Indianapolis, stated that he had operated on thirty-three cases of cholelithiasis and had never found a stone in the common duct and rather questioned the reported cases of others. I replied to him that he would probably find one in his next operation, as some surgeons reported less than 3 per cent. in the duct. Three days after I returned to my home, I was called to a woman, from Indianapolis, who had been having for years attacks of recurring pain in the epigastrium extending to lumbar and lower dorsal region, with rigors and fever, followed by tenderness over liver. She had slight jaundice, which deepened at time of attacks—clearly a case of movable choledochus stone. Her Indianapolis physician had made the diagnosis of stone in the duct, but the patient had declined to consult a surgeon at that time.

Courvoisier estimates that in two-thirds of the cases there is but one stone. Mayo Robson's experience shows a much larger proportion of multiple calculi in the duct. In about two-thirds of the cases the stone is in the duodenal end of the duct, and, of the remaining third, the stones are divided about equally between the hepatic and middle portions of the duct. Fenger's valuable studies on movable choledochus stone have been extremely helpful.

In a small per cent. only of cases can the stone be pressed from the duct into the duodenum or manipulated into the gall-bladder, but this should be attempted when it seems at all possible—especially where the gall-bladder has been opened, and after the stones have been removed from the bladder and the cystic duct.

Choledochotomy *without suture* is called for in the large majority of common duct stones. Suture of the duct may be practiced in the absence of marked cholangitis, if the patient's condition has not been rendered serious by much suffering and protracted jaundice and if the duct is enlarged. Gauze drainage should be resorted to in all cases, it matters not how carefully the stitching of the duct has been carried out. The time required for suturing the duct adds very greatly to the gravity of the operation in cholemia of long duration, and it would be contrary to surgical practice elsewhere to suture when "offensive muddy bile" escapes from the duct. Kehr refers to several cases which recovered after the giving way of the duct sutures, when death seemed imminent before the offensive discharge appeared. When there are extensive adhesions in the locality of the duct, the wound in choledochus should be left open and gauze used, even though the patient's general condition would warrant a protracted operation, in order to relieve the cholangitis, which may extend if the duct is closed. Kehr insists that the surgeon must be guided by the pathologic condition as to suturing or draining. He says tampon in all cases, "but never suture if the bile is muddy and cholangitic symptoms have preceded." Morrison's pouch, which will hold nearly a pint of fluid, makes drainage in this location entirely satisfactory. The lumbar stab is preferred by some surgeons, but the entire safety of transperitoneal drainage has been abundantly demonstrated.

Unquestionably choledochotomy *with suture* is being more and more supplanted by the open treatment of the duct and the mortality is being correspondingly lowered. Kehr, who has done more gallstone operations than any other surgeon, claims that he first advised the open treatment of the duct, but we know that he is in error, as the operation has been advocated in this country since the early part of 1892, at which time experiments were conducted by me on lower animals and reported to the American Medical Association. At that time and for some years afterward it was admitted by surgeons that the operation would succeed on normal organs with normal bile, but not otherwise. I afterwards induced pathologic changes in the biliary passages and demonstrated that the operation was successful in infected cases. Experimental and clinical experience demonstrates conclusively the safety of the operation.

Courvoisier is credited with the first choledochotomy, which was done in 1890, the duct being sutured. Marcy, however, reports a case in which he sutured the duct, in 1889. For a few years after this in a limited number of cases where the duct was inaccessible or where it was found impracticable to suture, it was drained, but the operation was regarded as being very incomplete and unsatisfactory. McBurney was the first to advocate the removal of stones impacted in the duodenal portion of the duct through incision in the duodenum.

1. Prof. Kher's Introduction to the American Translation of his book on Gall-Stone Diseases.

Kehr's record of 97 choledochotomies with 6 deaths is remarkable and is due to his having drained in extreme exhaustion and cholemia and where there was marked cholangitis. Much of his success, he claims, is due to his great experience in operating, which has enabled him to better master the technique. He says he now does choledochotomies in a half-hour which formerly required two or three hours. As but few operators can have this great clinical experience with gallstone disease, I would advise those who only occasionally operate for cholelithiasis to induce pathologic changes in the biliary reservoir and passages in dogs and by operative procedures to correct them. Dexterity in operating and greater familiarity with this class of surgery may be had in this way.

At the Indianapolis meeting, two years ago, I reported two cases in which hepatotomy had been done in obstruction to the biliary passages, and at the Pan-American Medical Congress, in Havana, presented the abstract of a paper on this subject. The operation is indicated in cases of obstruction with enlarged liver, where the gall-bladder or ducts can not be isolated, or the patient's condition from exhaustion and cholemia will not permit of a protracted search for the bladder or ducts. It will be only exceptionally called for and the cases will be fewer as the surgeon's experience increases in choledochus operations; he will then be enabled to better locate the bladder and ducts so much changed by inflammatory processes. After the patient has been relieved of cholemia by the escape of bile from the incision in the liver, an operation with less danger may be done for the removal of the obstruction in the duct. In addition to the above indications I think the operation should be resorted to in hepatitis before it has reached the stage of pus formation, if the liver does not rapidly become smaller after drainage of the biliary reservoir or the ducts. My attention was first attracted to the value of the procedure in a case in which the amount of pus removed was not more than one-half ounce, but in which the division of the biliary canals resulted in the escape of large quantities of bile for many weeks.

The patient was seized with violent pain over the region of the gall-bladder and required a hypodermic of morphin, ¼ grain, before being relieved.[2] The liver was tender and extended an inch and a half below the margin of the ribs. The skin was slightly discolored. There was nausea and some vomiting; temperature was 102 in the afternoon, on the next day 99.5 in the morning and 100.5 in the afternoon; the pulse was less than 100. The daily temperature remained the same for a week, everything pointing to an abscess of the liver. On October 28, 1898, one week after the attack, the abdomen was opened and the right lobe of the liver aspirated, not more than one-half ounce of pus being removed. I made an incision and with the finger searched for this small cavity; in so doing a wound of considerable depth and great size, perhaps two inches in length, was produced. There was very profuse hemorrhage, which was controlled by iodoform gauze packing. The liver tissue gave way under the packing, making the wound much larger. The patient stood the operation well. A large quantity of bile was discharged through the gauze, necessitating the frequent change of dressings. The bile continued to pass in large quantities for three weeks and in small quantities for another two weeks, about the amount usually discharged in a case of cholecystostomy. The liver rapidly decreased in size, and the patient is in better condition now than for several years. The extensive wound of the liver evidently assisted in his recovery by severing the small biliary canals and emptying the liver.

I did a hepatotomy on the following case with choledochus stone:[3] Mrs. S., of Shelby county, aged 28 years, consulted me in December, 1898. She had suffered from attacks of epigastric pain and fever for four months. There was some tenderness elicited by pressure over the liver, the margin of which extended to midway between the ribs and umbilicus. There was no enlargement of the gall-bladder. Several attacks of pain would occur in a day or a week, coupled with slight jaundice. There would be nausea and some vomiting. The chills and fever simulated malaria. The diagnosis of a stone, loose in the common duct, was made. Operation was advised as soon as the present attack was over. In a few days, however, she was seized with violent pain in the right hypochondriac region, with fast pulse, 130 to 140, temperature 103, and vomiting. The peritonitis was localized. It was decided to perform a drainage operation to bridge the patient over, and subsequently the operation to remove the stone. There were extensive adhesions to the under surface of the liver which were partly separated. There was no pus around the liver, but great bleeding occurred, which was controlled by gauze packing. The right lobe of the liver was aspirated, and it was thought that some pus was removed, but a more thorough examination showed that this was incorrect. Free incision was made in the right lobe, which was followed by considerable bleeding. Iodoform gauze was packed in the liver wound. There was considerable discharge for some days, of a dark bloody fluid, not a great deal of bile. The liver returned to its normal size in a few weeks, but there was occasional recurrences of epigastric and subscapular pain with fever, showing that the stone was still in the duct. The spleen became very much enlarged four months after the operation. About two months later, when the patient had decided to have the radical operation for the removal of the stone, it was passed. Patient was entirely relieved.

Hepatotomy was done in the following case[4] for the relief of cholemia in obstruction of hepatic ducts: Mrs. H., of St. Clair county, was referred to me by Dr. J. W. Ash, Springville, Ala., December, 1898. The patient was aged 60. Six weeks previously, without great pain, she rapidly became jaundiced. The jaundice gradually became more intense. Liver extended almost to umbilicus. There were no nodules to be made out. The patient's condition was extremely unpromising, and no encouragement was given the family. An exploratory operation was done December 31 and the gall-bladder was found empty and quite white. No stone could be made out in the common duct. A thorough investigation of the under surface of the liver was not made, owing to the very critical condition of the patient and the size of the liver. However, it was evident that the obstruction was in the hepatic duct or its branches. The bladder was attached to the abdominal incision more to anchor the liver than otherwise. An incision was made in the right lobe and the bleeding was free, but controlled by iodoform gauze packing. The patient lived five days and died from exhaustion. I had hoped to sever some of the biliary canals and thus drain the liver till the patient

2. Wounds of the Liver and Biliary Tract. Vol. xii, Trans. American Assn. of Ob. and Gynecologists.

3. Ibid.

4. Ibid.

was somewhat relieved of cholemia. There was a free discharge of very dark colored bile. The autopsy revealed a large malignant nodule in the transverse fissure, which completely obstructed the branches of the hepatic duct. The biliary canals throughout the liver were very much distended.

In July and August of this year, 1898, I conducted a number of experiments on dogs to determine the value of incisions in the liver in relieving biliary obstruction.[5] Five dogs were killed and the liver injected with fluid either through the gall-bladder, the common duct having been tied, or through the common duct. Incisions were then made in all parts of the liver, with the result that streams of the fluid would issue from the bile canals and there was general oozing of the fluid from the wounded surfaces of the organ if much force were used. Six dogs were anesthetized and the liver injected as above and this fluid with blood would flow as a rule freely when much force was used in injecting the fluid. Four had the common duct tied and after twenty-four hours the same experiment was conducted under anesthesia with similar results. In nine the common duct was ligated and gauze packed around the field of the gall-bladder and ducts. After from twenty-four hours to a week the liver would be incised in one or more places and as a rule the bile escaped satisfactorily through the gauze. It would be very dark after prolonged obstruction. Two of the dogs died, and the others were killed in from five days to two weeks after the second operation. Before killing them and while under the anesthetic, fluid was injected through the bladder or duct, and would flow from the wounds which had been made in the liver at the second operation, and also from incisions made at that time. Five had the gall-bladder removed and cystic and common ducts ligated, but as gauze was not used at the time of the operation to wall off the general cavity, they died in from twenty-four to forty-eight hours from shock and from the escape of bile from the liver where gall-bladder had been removed—the obstruction in the duct forcing bile from the liver.

Other experiments were conducted, but they added nothing to the above. While, as I have stated, the field for hepatotomy in gallstone diseases is very restricted, yet in those few cases it offers the surgeon much assistance in bridging the patient over till in better condition for a radical operation.

As we advance in the surgery of the ducts the field for cholecystenterostomy grows smaller. Certainly it should not be done, leaving a stone in the duct. Malignant disease and agglutination of the duct call for it. The Murphy button makes the operation quite simple.

Treatment of Hypertrophic Rhinitis with Zinc Chlorid.—A few drops of a 10 per cent. solution of zinc chlorid injected under the mucous membrane, is an effective means of curing hypertrophic rhinitis in those cases in which the swollen mucous membrane is smooth, soft and easily depressible, and by its distention over the lower turbinals obstructs the nasal passage. When it is thick and resistant this method has no chance of success. Viollet reports in the *Gaz. Hebd.* of August 18, that he has thus cured 5 out of 8 patients, the improvement unaltered for more than a year to date. His experience is much more extensive, but he omits those not scrupulously traced. His failures were due to his ignorance at first of the conditions of success as above described.

5. Experiments were conducted at the Birmingham Medical College, and I was assisted by Dr. R. E. Hogan, Assistant Professor of Gynecology and Abdominal Surgery.

Original Articles.

THE ROLE OF THE MYOCARDIUM IN PERICARDITIS.*

ALFRED STENGEL, M.D.

PROFESSOR CLINICAL MEDICINE, UNIVERSITY OF PENNSYLVANIA.

PHILADELPHIA.

Pericarditis is a condition of danger in any one or all of the following ways: 1, as a focus of infection; 2, as a cause of mechanical or reflex disturbance of the heart action; 3, as a starting point for a spreading inflammatory lesion.

As a focus of infection its danger is greater than is that of pleurisy or possibly even of peritonitis. The exudations of the pericardium are habitually more hemorrhagic or purulent than are those of the pleura in similar or the same infection and the clinical indications of general infection are also significant of a more virulent process.

The mechanical dangers are usually of little consequence, and, as has been found in the case of endocarditis, wider knowledge gives evidence that the circulatory disturbances of pericarditis are occasioned by changes in the heart muscle to a much greater extent than by mechanical or reflex disorders of the organ. The association of endocarditis with pericarditis is especially common in childhood, and either process may be the primary or they may occur simultaneously. The resulting condition is generally a heart so crippled that the continuance of life beyond the time of adolescence is purchased at the price of the extremest watchfulness. Fortunately, this association is not a very common one.

I hasten to explain that my reference to the two conditions, endocarditis and pericarditis, in such a way as to indicate that they constitute a pathologic entity, is largely out of deference to usage now somewhat antiquated. There are cases that we may on this ground term endo-pericarditis, but the essence of the malady is a "pancarditis" and its dangers are proportioned to the completeness with which the whole of the heart is involved. There are cases of pericarditis with very slight involvement of the underlying muscle, cases with considerable muscular disease and slight endocarditis, and finally, instances of severe involvement of all three. The last are the cases that have customarily received the name endo-pericarditis.

The myocardial element has not been unrecognized by the pathologists, but clinicians are only beginning to realize its significance. Chronic myocardial disease as a cause of clinical symptoms does not constitute a new conception. The degenerations have long been looked upon as important clinical conditions; of these, curiously enough, fatty degeneration has until recently fairly monopolized the clinician's attention, though the far more important condition is fibroid degeneration or inflammation. This may be independent of any other cardiac disease or it may be associated with endocarditis or pericarditis. The independent form is of greatest interest at the present time because its development is less clearly known, and its existence is less certainly recognizable. This independent myocardial fibrosis, or myofibrosis cordis, however, is not a matter of special interest in our discussion.

* Read in a Symposium on Pericarditis at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section

Of more importance is the fibrosis accompanying chronic pericarditis or endocarditis. In these cases the myocardium becomes affected by direct extension or in consequence of circulatory disturbances. The terminal result of this condition, as in independent myofibrosis, must always be cardiac dilatation, if intercurrent disease have not prematurely terminated life. Before, however, this terminal condition has developed, clinical signs of failing circulation may arise as obscure indications of the myocardial weakness associated with the pericardial disease.

I shall not allude to the physical signs of simple pericardial disease, such as frictions, mammary or costal retraction, etc., but would recall the symptomatic and physical evidences of muscular incompetency in cases of combined pericardial and muscular disease. As in the independent myofibrosis, there may be a gradual loss of vigor, a premature senility, a tendency to irregularity of the heart to a peculiar grayish pallor, to gastric disturbances, etc., but all of these indications are less prominent than in the independent form because chronic pericarditis is more frequent at an early age, when the senile type of clinical manifestations are unlikely to occur.

The best evidences of myocardial association with pericarditis are therefore those derived from physical examination. First of all I wish to insist that marked hypertrophy of the heart develops in a surprisingly short time in acute cases. In a recent case in a boy of 9, I found such rapid enlargement of the heart that it seemed impossible that the enlargement could be other than dilatation. The autopsy, however, showed practically no dilatation and very great thickening of the walls. This enlargement, however, is not true hypertrophy; it is largely degenerative, and the clinical signs would indicate this. The pulse is weak and of low tension—out of all proportion to the degree of enlargement of the heart. The slapping, irritable impulse of Martius accompanied with a weakened and quick pulse is of prime importance in indicating myocardial association with the pericardial disease.

What I have just said refers especially to acute cases. The chronic cases are attended with less pronounced signs of myocardial disease, but it may be said with considerable emphasis that peripheral congestion or cyanosis, the peculiar enlargement of the liver that has been termed pericardial cirrhosis of the liver, the occurrence of dropsies and marked irregularities of the heart, are always indicative of associated myocardial trouble and therefore of grave prognostic significance.

I do not wish to be understood as saying that myocardial disease always accompanies pericarditis. In a strict pathologic sense there is probably always some involvement of the muscle of the heart, at least to the extent of slight sub-pericardial infiltration, but in a clinical sense the heart wall is often unaffected. It should, however, be recognized that even such slight myocardial disease may occasion striking signs and symptoms. Thus, Fisher has found great disturbance of the heart action and of the sounds—a Flint's murmur—when there was only a moderate sub-pericardial disease. In this connection I wish also to recall that Romberg has found in simple endocarditis thrombosis of the myocardial vessels and myocardial degeneration. This contribution is of very great importance, for in no other way could the marked disturbances of the heart's action be explained in cases of endocarditis with anatomically trivial lesions. I would couple this with what occurs in pericarditis. The symptoms of the latter are largely the result of the underlying myocardial disease.

We are thus forced to the conclusion of Jürgensen that pancarditis is the diagnosis of the future, its type may be endocarditic, pericarditic, or myocarditic, but the immediate result and the final prognosis are to a large extent dependent upon the degree of involvement of the myocardium. A few dangers, such as general infection, embolism or mechanical interference with the heart by extensive effusion, are independent of the condition of the heart wall, but, these conditions excepted, the important criterion for prognosis is the condition of heart muscle.

ADHERENT PERICARDIUM.*

ROBERT H. BABCOCK, M.D.
CHICAGO.

It is so manifestly impossible in the few minutes allotted to me to consider this subject in its entirety, and so many of the points bearing on this subject have already been considered by preceding speakers, that it seems best to restrict my remarks to the clinical aspects of this disease.

We meet with adherent pericardium in two forms: 1. as a result of pericarditis interna which has led to a more or less complete and firm union of the two layers of the sac, without adhesion to the surrounding structures; 2, as a result of pericarditis interna et externa which has caused adhesion not only between the pericardium and epicardium, but also between the sac and the contiguous structures, as the chest wall, diaphragm and lungs.

In this second form there is often such an extensive development of fibrous tissue within the mediastinum, with consequent union of all the structures therein contained, that the condition has been termed chronic adhesive or fibrous mediastino-pericarditis. In some cases this proliferation of fibrous tissue is not limited to the mediastinum, but invades the pleural and peritoneal cavities in the form of a general serositis.

Not only is the capsule of the liver thickened, but the connective tissue hyperplasia invades the organ, becoming especially marked in the interior of the lobules and in the fissure. In time this fibrous tissue undergoes contraction and the liver becomes reduced in size and hard, very much as it does in hepatic cirrhosis. The once enlarged and chronically congested organ shrinks, becoming dense and thin bordered, more or less granular, but still fairly regular in outline, excepting that its notch is greatly exaggerated. According to Eisenmenger, it is by the contraction of the connective tissue within the fissure of the liver and consequent compression of the portal vessels that the shrinkage in the size of the organ leads to ascites, the same as does the atrophy in Laennec's hepatic cirrhosis.

Finally, the adherent pericardium may exist without chronic inflammatory changes in the endocardium or myocardium, but in most instances it is associated with valvular disease, or with chronic myocarditis.

SYMPTOMS.

These depend not only on the extent and situation of the pericardial adhesions, but also upon the co-existence, or not, of other lesions as valvular defects. If the two layers of the sac alone are adherent, and particu-

* Read in a Symposium on Pericarditis at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section.

larly if the adhesions are limited in extent, cardiac hypertrophy may be the only effect and the circulation is carried on so adequately that no symptoms are produced. If, on the contrary, the two surfaces of the pericardium become adherent, while the heart is in a state of dilatation from acute myocarditis, or in consequence of valvular disease, and if the organ is therefore not able to return to its previously small size, the effect upon the circulation is eventually disastrous and symptoms due to stasis declare themselves.

If the pericarditis was external as well as internal and led to fixation of the sac to some of the surrounding parts, the heart is held more or less firmly as in a vise and is hampered in its work. Its systoles are less effectual than normal, since the fixation of its walls serves to hold the cavities in a state of distension, and its contents are imperfectly discharged. Stasis inevitably results. If to this condition is united a valve lesion, as mitral regurgitation, the effect is particularly bad and symptoms are not long deferred. It is for this reason that chronic, adhesive mediastino-pericarditis is so likely to prove a serious affection. In all cases there is much difference in the severity and manifestation of symptoms. In one individual these are referable chiefly to stasis within the pulmonary vessels, shortness of breath on exertion, cough due to bronchial congestion and a marked disposition to attacks of bronchitis. In another case palpitations either with or without dyspnea are called forth by effort and excitement occasioning much discomfort and it may be alarm. In these cases the pulse is apt to be persistently rapid, it may be irregular and the cardiac impulse is exaggerated in force and extent. In a few cases without co-existing valvular defect, the disturbance of circulation is not pronounced, being shown only by digestive disorders lasting for years, and attributed to simple dyspepsia or to chronic gastritis, but rarely to their proper cause on account of the obscurity of the pericardial lesion and the difficulty or impossibility of its diagnosis.

In most cases there is nothing to distinguish them from ordinary instances of mitral disease or from cardiac dilatation. Physical examination usually discloses enlargement of the liver from passive congestion. This enlargement is generally greater than one would expect from the cardiac findings, and I have been impressed by the obstinacy of this hepatic engorgement under treatment. It is not only difficult to reduce its size by ordinary means of treatment, but the congestion of the organ displays a striking tendency to recur as soon as treatment is abandoned.

I have had under observation for several years a female patient whose mitral valve leaks and whose enormously enlarged heart is apparently completely encased in fibrous tissue that binds down the organ on all sides, so that no amount of rest in bed or digitalis seems to reduce its size in the least. The liver has always been greatly engorged, extending for a long time nearly to the crest of the ileum, and requiring the daily use of saline laxatives to relieve the patient from pain and discomfort. For the past year the organ has been gradually diminishing somewhat in size and growing in thinness and hardness. This patient has displayed remarkably little dyspnea on effort, but is greatly annoyed by the pounding and tumultuous action of the heart, this sensation being specially noticeable in the epigastrium. Of late she has had a great deal of cough, difficult mucous sputum and upon several occasions slight hemoptysis. She has to be extremely careful in her diet, and her urine and menses have become scanty.

Another female patient with pronounced mitral insufficiency has pericardial adhesions that bind down the left side and base of the heart, fixing the apex beat immovably in place far to the left and downward, but the border of the right heart is apparently free from adhesions. Whereas the left ventricle never varies in size under any conditions, the right heart, as shown by the area of cardiac dulness, becomes dilated with the greatest ease and rapidity. The liver, which is persistently enlarged, fluctuates somewhat in size in accordance with the state of the right heart, but even when at its smallest always extends from 2 to 3 inches below the inferior costal margin, no matter how vigorous may be the onslaughts upon it by means of epsom salts. This patient's symptoms are not of the digestive organs, but are those of shortness of breath and a rapid pounding action of the heart and general weakness. The urine remains fairly abundant and the menses are too profuse and protracted. She is always promptly benefited by absolute rest in bed, a milk diet, cathartics and digitalis, although this last never materially slows the heart.

When in all such cases compensation finally gives way the breakdown is complete and irreparable. Symptoms of stasis declare themselves everywhere, but do not differ materially from those of cardiac asystolism from any other cause.

The most interesting class of cases are those whose clinical features resemble a case of atrophic cirrhosis of the liver in its terminal stage. These are the cases of chronic fibrous mediastino-pericarditis. They not infrequently pursue a latent course for many years, and even after symptoms have set in are not recognized as pericardium until they come to autopsy. This applies particularly to cases in which the pericardial synechia is unassociated with valvular disease. Not only is there chronic engorgement of the liver, but the contraction of the fibrous tissue interferes at length with portal circulation and induces serious symptoms.

The patient's attention is first attracted by an increase in the size and firmness of his abdomen. In some instances icterus accompanies, or even precedes, this increase of girth. At length, driven to seek medical advice, he is discovered to have ascites usually without edema of the lower extremities. The physician examines the heart and urine, detects no heart disease and discovers no albumin, but perhaps some bile. The case is put down as one of hepatic cirrhosis. The following is an illustrative case:

Not long ago I saw in consultation a man of 55, who had been intensely jaundiced for nearly two years, and in August, 1900, was tapped for ascites. This had rather speedily recurred, and had been reduced by apocynum cannabinum for a time, but had again been drawn off the morning of the day I saw him. He had suffered from articular rheumatism eighteen years before, but experienced no shortness of breath or other discomfort since. The thin bordered, dense, slightly granular feeling liver extended in the median line nearly to the umbilicus and from one costal arch to the other, being lost beneath the ribs just outside the right mammillary line. Owing to the recent paracentesis, the peritoneal cavity was free from fluid and there was no edema.

The cardiac area was somewhat increased to the right and downward, the sounds were clear and strong and free from murmurs. The apex beat was rather tapping in character, in the 5th left interspace within the nipple line, and there was not very well marked epigastric pul-

sation. In the 5th and 6th interspaces between the apex beat and sternum, and also in the sulcus between the ensiform appendix and left costal cartilages, a systolic retraction could be perceived both by palpation and inspection. Furthermore, when the patient was instructed to draw a full slow breath, the right external jugular could be seen to bulge out during the inspiration. This distension was also palpable. Pulsus paradoxus could not be determined. I had no hesitation in making a diagnosis of pseudo-cirrhosis of the liver, secondary to adherent pericardium. Such cases may run a protracted course, requiring repeated tappings, and the patients succumb to exhaustion, if not to the effects of stasis.

DIAGNOSIS.

Under some circumstances this may be one of the easiest of matters, in other cases it is one of the most difficult. Diagnosis is difficult, if not impossible, when the sac is adherent to the heart, but not to the neighboring structures. The signs then relied upon are, inspiratory distension, instead of normal inspiratory collapse of the external jugulars, or other superficial veins; diastolic collapse of the cervical veins, known as Friedreich's sign; pulsus paradoxus, a by no means constant or reliable sign; and the detection of cardiac hypertrophy for which no adequate cause can be discovered. When the pericardium is adherent to the chest wall or diaphragm other signs are often developed that render diagnosis easy and certain. These are, a systolic retraction of one or more interspaces in close proximity to the apex beat or of the epigastrium; fixation of the apex, so that its gravitation from side to side with the turning of the patient's body or its descent during inspiration is prevented, or much restricted; a systolic retraction followed by a diastolic rebound of the chest wall that, by some authors, is considered pathognomonic; a systolic sinking or drawing in of the 10th and 11th intercostal spaces below the inferior angle of the left scapula, and occasionally of the right, known as Broadbent's sign. These are all very significant and much more frequently discovered than are those previously mentioned. In some instances auscultation detects friction sounds of a fine crackling or creaking character along the sides or apex of the sac, which sounds are synchronous with cardiac contractions and are sometimes elicited only during inspiration. A fine creaking sound is heard in some cases at the base of the heart upon the body of the sternum, while the patient slowly raises and lowers the arms. The detection of such pleuro-pericardial, or even strictly pleural friction sounds, furnish indirect or corroborative evidence of the existence of an adherent pericardium, and, taken in connection with cardiac hypertrophy and hepatic engorgement, would render the diagnosis extremely probable, even in the absence of more distinctive signs.

Finally, in some cases in which positive signs can not be obtained, the diagnosis of this condition is rendered possible by a process of exclusion, together with the history of a previous rheumatic attack, and the discovery of an hepatic enlargement for which no other predisposing cause can be ascertained. The elaboration of this subject as well as the prognosis and treatment will have to be left to the speakers that follow.

Isolation Hospital.—Colorado Springs, after a fruitless endeavor to combine with El Paso County in the erection of an isolation hospital, has decided to build one for the city alone, at a cost of $2000.

TUBERCULAR PERICARDITIS.*

C. F. McGAHAN, M.D.
AIKEN, S. C.

This is a disease much more prevalent than has heretofore been generally accepted. A great many cases of obscure heart trouble in the anemic when we find no valvular disease, and when there are no marked, but certain masked symptoms of the disease, is due to tubercular pericarditis. Especially is this true if the patient later begins to lose weight and assume a cachectic appearance.

Tubercular pericarditis generally progresses insidiously. It is communicated to the pericardium through the lymphatics, arterial or venous systems, and from that tends to extend to the peritoneum and other serous membranes. It is difficult to diagnose the disease as tubercular pericarditis in contradistinction to the non-tubercular pericarditis, unless it is secondary to a demonstrable tubercular lesion. However, if we are in doubt we can examine some of the aspirated fluid for the tubercle bacilli. If our search were negative we could not be positive that the disease was not tubercular, for the bacilli are very hard to find. It would then be necessary to inoculate a guinea-pig with the fluid, observing precaution of asepsis and if, after death, the glands are found to contain bacilli the diagnosis would be tubercular pericarditis.

The exudate is generally of the plastic, fibrinous, cheesy, or purulent form.

The symptoms of tubercular pericarditis are those that we would expect from an enlarged and adherent heart, together with the general symptoms of malaise and more disturbance of the general system than is found in the simple pericarditis, or that secondary to rheumatism or one of the exanthematous diseases.

CASE 1.—Male, white, aged 19, had been under my care for phthisis. The disease started in the apex of the right lung and progressed to stage of cavity, which was on the right side, behind second rib. Case was quiescent; the cavity was contracting; expectoration lessening rapidly, and he had stopped having an afternoon fever and night sweats.

The case was progressing satisfactory until the patient suddenly complained of pain in left side, became short of breath; his pulse rose to over 160; temperature became high and there was dulness over whole of left side. Upon careful examination the voice sounds were found and some râles at the apex of the left lung. The area of heart dulness was greatly enlarged and the sounds indistinct; the to-and-fro friction sounds, so significant of pericarditis, were audible. There was slight bulging of the intercostal spaces, but there did not seem to be enough to aspirate, and as the patient was tubercular it was not necessary to examine the fluid. The patient gradually became worse from the general tuberculosis and died from tuberculous diarrhea. The valves remained good throughout the illness and the brain was clear. In the last week only did the urine show marked albumin.

The interesting points in this case were the sudden involvement of the left lung and pericardium, when the case was apparently progressing favorably. At first it seemed possible that pneumonia was developing, and it was only after careful examination that pericarditis was diagnosed. There was not the large amount of fluid which we generally expect to find in the tubercular pericarditis, and it is to be regretted the more on that account that a postmortem was not permitted. Tubercle bacilli were found in the sputum.

* Read in a Symposium on Pericarditis at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section.

CASE 2.—This patient was seen at St. Luke's Hospital through the kindness of Dr. Beverly Robinson. He entered March 19, 1901. Male, aged 38, American laborer.

Family history is negative.

Past history: He does not remember diseases of childhood, but has never been sick in bed since that time. No rheumatism, no tonsillitis. Drinks tea, coffee and much beer and whisky. No gonorrhea. Had chancroid several years ago, no other venereal disease.

Present history: Four months ago, after a debauch, he began to have pain in his right side, which was shooting in nature and increased on deep inspiration. No coughs, chills or vomiting. This pain lasted for a month, then he began to cough and raise small amounts of blood-stained mucus. This was accompanied by some fever, worse in the afternoon, and he also suffered from a great weakness, though he did not go to bed.

Two weeks ago he began to have similar pain in his left side and the cough grew worse. Very slight expectoration. At the same time he had pain in the cardiac region, and began to suffer from palpitation. Has been short of breath at times during the sickness, but he is not troubled with it now. Feet do not swell; eyes normal; urine normal, no stomach symptoms. Appetite is poor; bowels regular. Chief complaint is pain on both sides. He did not expect to remain in hospital, but only wanted something for the pain.

Examination: Rather large frame; well nourished; skin and mucous membranes of fair color; tongue broad, moist tremulous, slightly coated; pupils normal.

Heart: Right border 2¼ inches from median line; apex beat not felt; dulness in fifth space, 5¾ inches from median line. Pulsation of the whole left chest was felt. Heart action very rapid, 172. A superficial, high-pitched, systolic murmur was heard between nipple line and sternum in third, fourth and fifth left intercostal spaces; modified by pressure of stethoscope. No further murmur detected. Pulse very rapid, 172; it was regular, very small and weak. Lungs: Right lung had diminished motion; below clavicle vocal fremitus increased. Dulness increasing to flatness extended posteriorly up to spine of scapulæ. Feeble vocal and respiratory sounds; some bulging of intercostal spaces. Right chest at ninth dorsal spine, 17¾ in.; left chest, 19¼ in. Left side marked dulness near sternum in fourth interspace, clear fluid was found in ninth intercostal space. Rest negative.

Liver: Dulness begins in fourth space middle clavicular line, extends 2 inches below free border of ribs; edge felt at this level, firm, flexible, not sharp. Spleen felt 1½ inches below free border.

Inguinal and epitrochlear lymphatic nodes enlarged. Knee-jerks present; more marked on right side; no ankle clonus; some blueness of finger nails.

Patient improved greatly, and on April 25 some fluid was drawn from the pleura of the right chest for examination. A guinea-pig was inoculated with it on the same day, and on May 19 was killed and tubercle bacilli were found in the characteristic cheesy pus from the enlarged lumbar gland. Miliary tubercles were found in the great omentum, liver, spleen, kidney, lungs and on the abdominal parietal peritoneum.

Condition May 26: Patient is comatosed; breathing, Cheyne-Stokes in character. Right pupil reacts to light; the left pupil is oval in outline and does not react to light. No apparent paralysis of ocular muscles; only slight rigidity of back of neck. Paralysis of right hand and arm, skin cold and somewhat blue; no response to pin-prick over area of right hand, arm and right side of chest. Knee-jerk very slight on either side; no ankle clonus. No tubercle bacilli found in sputum or in fluid from pleura, although that they were present in the latter was proven by their presence in the guinea-pig.

Sanitary Progress in Spain.—Since the Spanish authorities appointed Dr. A. Pulido to be at the head of the national health department, a number of reforms have been instituted in regard to public hygiene. A decree that went into effect October 31 enforces compulsory declaration of all cases of certain infectious diseases. The list includes leprosy and tuberculosis.

CARDIAC LESIONS AS OBSERVED IN THE NEGRO, WITH SPECIAL REFERENCE TO PERICARDITIS.*

FRANK A. JONES, M.D.

Chief of Clinic, East End Dispensary; Demonstrator Physical Diagnosis, Memphis Medical College.

MEMPHIS, TENN.

In that class of colored people who come as patients to my outdoor clinic, syphilis, tuberculosis, and gonorrhea in a great measure constitute the trinity of diseases. It must then follow that renal, pulmonary and cardiac lesions are quite frequently observed, and constitute a field rich and ripe for the student of clinical medicine and physical diagnosis. In studying cardiac lesions in the negro, I have found that their classification and relative frequency does not correspond to those in the whites as described by our text-books on physical diagnosis. Briefly, I shall direct your attention to these lesions and as they occur in the negro.

Our text-books teach that mitral regurgitation is the most frequent of all cardiac valvular lesions, and that in 50 per cent. of cases it follows as a sequel of endocarditis, the results of acute inflammatory rheumatism. This rule, however, does not hold good in the colored race. From the 25,000 negroes that have come under my observation at the clinics during the last five years, I have had ample opportunity to reach conclusions. These conclusions justify me in stating that aortic lesions are much more common than mitral, aortic regurgitation standing first.

When we consider the vascular changes in aortic regurgitation, the accompanying arteriosclerosis; when we reflect that syphilis, alcoholic abuse, muscular strain, improper food, faulty elimination, etc., play a leading rôle in the pathology of both aortic insufficiency and arterial sclerosis, it can readily be seen why the negro should become subject to lesions arising in and around the aortic valves. The classis corbovis reaches its highest degree of development in the negro with aortic regurgitation, and also in interstitial nephritis. In every postmortem that I have witnessed where aortic regurgitation had been diagnosed during life, where a general atheroma, a well-marked arteriosclerosis, a calcareous degeneration of the aortic valves and arch of the aorta, with evidence of previous atheromatous patches, where there was the contracted kidney of interstitial nephritis, and the large hypertrophied ventricle, the typical corbovis has been found. The youngest subject with the above-described conditions was a colored boy 16 years of age. He had a well-marked syphilis, also tuberculosis during life. Vascular changes are so great in the negro race that Dr. Osler informed me last year, while I was visiting the wards at Johns Hopkins University Hospital, that he had observed it so commonly in the negro that they had named one of the wards Corrigan's.

Syphilis and tuberculosis are boon companions, the mighty monarchs in the production of all classes of cardiac lesions arising so frequently in the negro. A marked feature in aortic regurgitation with the accompanying arteriosclerosis is the absolute absence of dropsical symptoms. I have seldom observed it. Angina pectoris is quite common. Sudden death is the rule. I note that one of our modern text-books on practice says that aortic regurgitation, considered as a whole, is the

* Read in a Symposium on Pericarditis at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section.

least dangerous of all valvular lesions, and one in which a favorable prognosis may be given. My experience with this lesion both in the whites and the blacks has made me skeptical as to prognosis. The majority of my patients with this condition have died suddenly. It is exceedingly fatal in the negro, death coming on suddenly before symptoms of failing compensation become manifest. Broadbent, Sampson, Cheadle, Sibson, in fact nearly all the authorities on diseases of the heart with the exception of Walsh, agree that aortic regurgitation is the most fatal of all cardiac lesions.

With reference to frequency aortic stenosis stands next to aortic regurgitation in the negro. I have frequently found them co-existing. The "hoo-chee" or steam tug murmur denoting stenosis and incompetence. I have often demonstrated to the entire satisfaction of my class and to physicians who were inclined to doubt this important auscultatory physical sign. The same conditions that operate in producing regurgitation at the aortic valves are found in stenosis. The integrity of the heart muscles is taxed to its utmost in these conditions.

The myocardium and endocardium, in fact the whole cardio-vascular system suffers the brunt of specific infection; in proportion to the degree of infection, the constitutional symptoms will be manifest. Text-books state that the murmur of mitral regurgitation is the one found to be most frequently musical. In the negro this is not correct. I have recorded 8 musical murmurs, 7 were at the aortic valves with unmistakable physical signs of aortic regurgitation, the murmur occurring with diastole and not with systole. In aortic regurgitation the high blood tension, the tumultuous action of the heart, the arteriosclerosis and the calcareous degeneration in the aorta are physical conditions conducive to musical murmurs. The venus hum in acute febrile conditions is much more frequent in the colored race than in the white.

Let us now touch upon mitral regurgitation. A close review of my cases shows that it does not occur as often as aortic regurgitation and aortic stenosis. Much has been written of late about the murmur of mitral incompetency. Two types have been well defined, especially so by Broadbent. One in which the mitral valve is incompetent from structural changes due to inflammatory action extending from the endocardium, the incurable mitral. The other due to dilatation of the ventricle, occurring in anemia and acute febrile disorders, the curable mitral. These two types are seen quite often at the outdoor clinic.

While we recognize that endocarditis following acute rheumatism is the most frequent cause of mitral regurgitation in the white, I have in the majority of cases failed, after the most careful examination, to elicit a history of a previous rheumatism in the negro. In those cases in which the symptoms and physical signs were well marked, where their previous health had been good, I have in the great majority of cases found an active syphilis operating; an acute syphilitic infection, if you please. My observations force me to the conclusion that acute syphilis has more to do with the production of mitral regurgitation in the colored race than inflammatory rheumatism.

Syphilis in the negro is quite often precocious. It is not an uncommon thing to see the classic stages merge rapidly one into the other, the chancre, the bubo, the eruption, the mucous patch in the throat, the periostitis, and the syphilitic fever existing simultaneously. This precocious syphilis is an index of active systemic infection and intoxication. The entire cardio-vascular system becomes overwhelmed, consequently syphilitic endocarditis, myocarditis in the production of mitral regurgitation. In this class of patients I have found the prognosis good. Remove the cause by eliminating rapidly the specific poison and your patient makes a fairly satisfactory recovery.

In that class of patients where symptoms of failing compensation are out of proportion to the physical signs, the prognosis is grave. A general anasarca comes on rapidly. The pericardium, the thorax, the peritoneum becomes filled with an enormous quantity of transudated serum. The patient literally drowns in a sea of self-generated fluids.

What is the pathologic significance in these cases? Quite often a history of a recent syphilis with an acute parenchymatous nephritis can be obtained, the cardiac it seems being secondary to the renal lesion. Tuberculosis will in the majority of cases be engrafted upon this specific history. I have often seen tuberculosis develop just as these dropsical symptoms were becoming manifest and run its course rapidly. The postmortem showed cavities in the lungs, marked degenerative changes in the endocardium and myocardium, and the kidney of diffuse parenchymatous nephritis. General anasarca, whether it be due to cardiac or renal lesions, is much more pronounced in the colored race than in the white.

Text-books are exhaustive in describing the physical signs and symptoms of mitral stenosis. Broadbent describes the three classic stages in detail. After a most careful and searching examination I have yet to find it in my clinical work in the negro. I have had it suggested to me that I had confused it with aortic regurgitation. The physical signs of aortic regurgitation with the accompanying arteriosclerosis are so well marked and defined in the negro that the most superficial observer could recognize it if he had any knowledge whatever. Pain in the chest, shortness of breath, palpitation of the heart, with the physical signs of diffuse apex beats are very often expressive symptoms of a previous aortitis, a chronic endocarditis and dilatation. The triple infection of gonorrhea, tuberculosis and syphilis make that class of negroes who attend the outdoor clinic ideal subjects for the study of valvular lesion of the heart, also pulmonary and renal lesions.

Now, with reference to the latter clause of my subject, a special reference to pericarditis, I have not the time in this paper to give it the thoughtful consideration it demands. I wish, however, to call your attention especially to pericarditis occurring in the negro during an attack of pneumonia. Pneumonia with him, as most of you know, is quite fatal. Given an acute attack of lobar pneumonia, a close physical examination will reveal an existing pericarditis. Its absence in the negro during an attack of pneumonia is the exception and not the rule. Purulent pericarditis is much more common than is generally supposed and I fear often goes unrecognized. I have observed it in the negro varying from the ages of 8 to 75 respectively.

A colored girl 8 years of age with rickets, with Hutchinson teeth, with saddle-shaped nose, and with a history of hereditary syphilis, came under my observation during the summer of 1899. A diagnosis of bronchitis and malarial fever had been made by another physician before I saw her. The apex beat could not be found. Upon auscultation the heart sounds were distant. Inspection showed marked bulging of the precordia. The

percussion note was absolutely flat over the whole apex area; dyspnea was marked. Temperature ranged from 102 to 104 F.; sweats and rigors as of a general sepsis were present. Aspiration revealed pus. She died the following day. No autopsy could be had.

A colored man 76 years of age was brought to my clinic during the spring of '98. He had suffered a severe attack of la grippe in the previous January. Physical signs and symptoms were characteristic of pericardial effusion. He had no fever. I aspirated with a small needle and withdrew pus. Symptoms of suffocation were so urgent that an operation was immediately decided upon. An incision was made and about a teacupful of pus evacuated. He died in a few hours. The relatives would not permit autopsy. These two cases are cited only as examples of purulent pericarditis in the negro which frequently come under my observation. I can not touch here upon adherent pericardium.

The following are the cardiac lesions in the negro in the order of their frequency: 1. Aortic regurgitation in the negro is the most frequent, the most dangerous of all valvular lesions; 2, aortic stenosis is next in frequency; 3, mitral regurgitation next; 4, mitral stenosis has not been diagnosed from physical signs and symptoms; 5, tuberculosis and syphilis act both as exciting and predisposing causes in the production of muscular and valvular lesions; 6, syphilitic history in mitral regurgitation is more frequently found than is a rheumatic history, and 7, the murmur of aortic regurgitation most frequently musical.

SOME POINTS IN THE TREATMENT OF PERICARDITIS.*

FRANK P. NORBURY, M.D.
JACKSONVILLE, ILL.

In the beginning of my pathologic experience in hospital service, it was a surprise to me to find how frequently evidences of former pericarditis occurred. Later, as my clinical experience increased, I found how easy it was to overlook this disease, and how in letting it go unrecognized, inadvertently good treatment was frequently practiced by the absolute rest given the patient. The primary disease being under surveillance, the secondary was of necessity under conditions favorable for recovery. This experience suggests our only real available means of prophylaxis, viz., good care of the patient during the continuance of the primary disease, anticipating the fact that pericarditis is usually a secondary affection.

It then behooves us in the treatment of rheumatism, acute infectious fevers and septic processes, to keep ever in mind the possibility of pericarditis as an aftermath, and govern ourselves accordingly, by insisting upon absolute rest and quiet until this danger is passed. This is the limit of prophylaxis, except in rheumatic affections, when the liberal use of salicylates will do much toward rendering assistance in obviating this complication.

GENERAL TREATMENT.

Pericarditis should be regarded and so treated, as a serious disease, even if the symptoms are slight. Each case, it is true, must be treated upon its individual merits, but in a general way all must come under the absolute rule of enforced rest and quiet surroundings. The active business man, the busy housewife, the restless child, one and all, must be put under favorable conditions for the rest treatment.

I recognize how easy it is for us to lay down rules in such cases and how easily the patient can break them. Just recently one of my patients took upon himself, during the progress of convalescence, the responsibility of leaving his room to direct some simple household measure. An attack of dyspnea with marked dysphagia followed, throwing him back into bed and prolonging his stay in his room. It is as difficult to control an active business man as it is a child. The child we can confine to his bed for a prolonged period, but the man frequently takes the reins himself and suffers accordingly.

To reiterate enforced rest is necessary because it curbs the symptoms and places the patient under the most favorable conditions for speedy recovery.

DIET.

It is important to be especially careful of the diet of the patient. Milk is the most suitable diet—in fact, "It is," as said by Gibson, "absolutely indicated." Especially is this true where dyspnea is a feature. Hemmeter says: "I have noted several deaths in patients suffering from cardiac disease, shortly after a full meal, and a meal that was apparently enjoyed." I know in my own experience, while teaching clinical medicine, of such a case.

In giving milk it is better to follow the rule of giving a small quantity every two or three hours rather than load the stomach with a larger quantity less frequently. This is a simple matter, but very often ignored, and because of the gastric disturbances occurring in pericarditis, are prominently set forth after over-indulgence: it is possible to guard them as leading symptoms of disease of the stomach. Two cases, diagnosed gastritis, have come under my observation in consultation which were cases of pericarditis.

The irregular heart action was attributed to dyspepsia, whereas the passive congestion inducing gastric disturbance was due to the pericarditis. Careful dieting will overcome this feature, while at the same time it will promote the nutrition of the patient, which must be maintained.

SYSTEMIC TREATMENT.

The etiologic factor is to be considered in the systemic treatment of pericarditis. In cases due to rheumatism it is especially important to give the salicylates, as before stated under the head of prophylaxis. By so doing we are at least giving every assistance toward resolution, coming within the therapeutic possibilities of these drugs.

It is well to remember that most all cases of rheumatic pericarditis get well, if we will let them alone. Keep them at rest and carefully meet indications as they arise.

SYMPTOMATIC TREATMENT.

Our therapy is to be directed more especially toward giving the patient comfort, relieving him from the distress of pain, promoting sleep, and being watchful of the little things which contribute so much to success in internal medicine.

Pain is usually the most striking symptom calling for relief. Sometimes a blister over the pericardium will be sufficient, or if it continues, cold applications, cold cloths or an ice bag used as needed. The continued cold has proven of service to me, not only in relieving pain, but also in promoting resolution by seemingly ar-

* Read in a Symposium on Pericarditis at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section.

resting effusion. Hot applications may be suggested in these few cases, where cold is not tolerated. The hot water bag, when the dysphagia is not sufficient to require the patient to remain in a sitting posture, or the use of hot cloths, or dry heat in other forms as suggested by the needs of the case, will be of benefit.

Morphin may be given where these means fail, or for that matter it is good treatment to give it at once, if the symptoms are distressing. I have given it for several days at a time, guarding it with proper cardiac support.

The patient is usually restless and, if a man, it is with more or less difficulty that we curb this feature, unless we use the bromids in moderation. The bromids are best given in the form of bromid of soda. This should be given during the day, usually commencing about noon, again at 4 or 6 in the afternoon and at bedtime. I find this is very frequently sufficient to quiet the patient, and usually promotes sleep at night.

Sleep is of great importance and should be watched carefully, as insomnia in one of my cases of rheumatic origin became an alarming complication. Cerebral symptoms, with hallucinations, delusions and fear of death, were conspicuous. Under such circumstances trional is indicated; it will promote sleep, and does not interfere with the heart's action. I used in the case just mentioned the combination of trional with sulfonal, the former promotes sleep quickly, while the latter is slow in action, but its effects are prolonged.

The heart may need to be helped, especially if the action is labored or irregular. In this case strychnia may be given, or if further stimulation is necessary, digitalis with strophanthus. I have used digitalis and strophanthus in a diuretic menstruum, believing free diuresis will assist in relieving the laboring heart. It will also assist in relieving cardiac distress, to flush the bowels with a free saline purgative.

To properly care for the effusion is one of the prime essentials of treatment. Caution in procedure is one of the lessons which the young men should learn, for I believe meddlesome interference causes more trouble than completely ignoring the effusion as a factor in treatment. The tendency of the effusion is to be absorbed, hence we had better let it alone. Be watchful, but only interfere when the indications are pronounced.

If the effusion is moderate, unless septic, it will be absorbed, and even if large, the chances are that with cautious use of diuretics and purgatives, it will disappear. I have frequently noticed in cases of delayed absorption that if we give calomel in small doses repeated for a prolonged period, the effusion can be relieved. The same holds true in pleurisy.

If we have to deal with renal complications it is imperative that we be exceedingly cautious. Baginsky recommends the application of ichthyol ointment over the pericardium, to facilitate absorption. He says that it is especially serviceable in children.

The local use of leeches and blisters act well in some cases and turn the tide in delayed absorption, but as a rule they are of little service.

SURGICAL INTERFERENCE.

In this day of improved surgical technique paracentesis is more frequently resorted to, in order to relieve the burdened heart where effusion is extensive. The indications for interference are, according to Osler, "dyspnea, small, rapid pulse, dusky anxious countenance," and we will add, the physical signs of extensive effusion.

Gibson says: "The considerations which have to be borne in mind in connection with paracentesis cardii are the determination of suitable cases, the selection of the most favorable site for operation and the best method to be adopted." He recommends as the most suitable site the fifth intercostal space just inside the mammillary line.

The aspirator is recommended, but as these questions are largely surgical, I prefer to have the surgeon assume the responsibilities in such cases. Even surgeons, however, do not agree as to the best means of operation or the most favorable site.

Brentano[1] maintains that tapping is dangerous, and holds there is no accurately determined and fixed space where the pericardial sac can be tapped without risk. He says the heart is lifted upward and forward against the chest wall by the effusion. He resects the fifth costal cartilage, punctures the pericardium, then incises, etc. He irrigates, in purulent cases, with a hot normal salt solution. "Where previous cardiac disease has existed operative interference is contra-indicated," he says.

The surgical technique and mode of management of purulent cases, as before stated, are features wholly within the province of surgery and as such are receiving notable attention. Ogle and Allingham[2] prefer to enter the pericardial sac from below through the diaphragm, and give in detail the steps of the operation. Roberts, in 1899, compiled statistics of the cases treated by surgical means, and, considering the gravity of such cases, the report shows encouraging results.

420 West State Street.

DISCUSSION FOLLOWING THE SYMPOSIUM ON PERICARDITIS.*

DR. DE LANCEY ROCHESTER, Buffalo, N. Y.—I think that if we carefully study this question that we will find that rheumatism, pneumonia and chronic disease of the kidneys are the chief factors in producing pericarditis, and if we try to analyze a little bit more carefully I believe that we will find that, in all those diseases, the active factor is a toxemia. It seems to me that the toxemia is the active factor rather than the infecting organism themselves and, therefore, in pneumonia, in rheumatism, etc., it strikes me that the toxemia should be given the first rank in the production of pericarditis. This toxemia causes, in most cases, a very powerful effect upon the muscular tissues, especially the myocardium. We know that in cases of pneumonia resulting in death that the fatal result when not due to the complications, or to the great involvement of the pulmonary structures, is due to the giving out of the heart, i. e., the myocardium; this explains why so many cases of pneumonia that have a pericarditis associated are fatal; the toxemia present attacks the heart muscle, which is already embarrassed by the pericardial involvement. In pericarditis a most important factor, so far as the prognosis is concerned, is the involvement of the myocardium.

In regard to the diagnosis of pericarditis, we know that in cases associated with pneumonia, ordinarily there is a very marked change in the ratio between the pulse and the respiration: in cases of pericarditis this change in this ratio is not maintained, the pulse increasing in frequency. A careful study of the precordium will indicate to us whether the myocardium or the pericardium is involved. The study of the pulse in its relation to the respirations is very important in studying pneumonia in connection with pericarditis. In rheumatism we have commonly the pulse decidedly frequent, soft and without any of the variations associated with respiration excepting the increase in frequency; but, in rheumatism, with the increase in temperature, one should look out for involvement of the feet, or other structure; it should also make us sus-

1. Progressive Med., March, 1900.
2. London Lancet, March, 1900.

* For the other papers in this Symposium, viz., those of Drs. Billings, McFarland and Preble, see issue of December 7.

picious of involvement of the heart structures. With these points regarding the pulse and the respirations I think we have a guide as to the association of the pericarditis. Either one of them being present should direct our attention to the cardiac region. In addition to that, instead of pain, substernal distress is much more pronounced, as a rule, than the pain. Then, too, the presence of the friction rub and the position of the apex beat, i. e., the position where we feel the apex beat, is of value.

In regard to the treatment of this condition there are two things that have been spoken of. If toxemia is to be recognized as the bottom of the cause of the pericarditis, then all our efforts should be directed toward the relief of that toxemia, and the avenues for relief here are the skin, bowels and kidneys; the lungs can not aid us. If we can stimulate the activity of the skin, bowels and kidneys we will aid in relieving the toxemia and overcoming the process of pericarditis. Sweating is very important and a valuable aid in keeping down the condition of toxemia and preventing pericarditis. In cases of pneumonia, the kidneys may be made to act very freely by the giving of large quantities of water and not by the administration of the diuretics, for the reason that the kidneys are, to a certain extent, inflamed and should not be stimulated by diuretics. Calomel is better than salts in keeping the bowels open; it also opens up the liver and so assists in relieving the toxemia.

So far as the local treatment of pericarditis is concerned, in the early stages of congestion I think we get better results from the local use of leeches. I think that leeches are thrown aside too much when they could be of great value. Again, we can use the wet or the dry cups. I have seen postmortem the local value of dry cupping. It should be done thoroughly and not only the skin raised up, but the skin and subcutaneous tissue should be well brought up into the cups until the skin is blue or purple and then you will get good results from the dry cupping.

DR. JAMES J. WALSH, New York City—We can accomplish very little by treatment. The story told of the Irish surgeon, Corrigan, of water-hammer-pulse fame, has its application today almost as much as in its own time. It is related that one of his assistants failed to notice the existence of a pericarditis in a patient and was profuse in his apologies for his negligence when Corrigan pointed it out. Corrigan said in his own dry way, "It's just as well that you didn't discover it; for, had you found it you surely would have treated it. Treatment usually does as much harm as good."

Even in our time, however, despite the advances in diagnosis, pericarditis is sure to be missed some time. Dr. Billings' cases are as good a proof of this as we would well have. It is no sign of negligence when in a complicated case a pericarditis fails of recognition. Mistakes of diagnosis, however, in this matter are mainly due to failure to suspect the presence of a pericarditis and so neglect to elicit the physical signs.

The important question for the diagnosis of pericarditis is the knowledge of conditions that should arouse suspicion of the presence of an inflammation of the pericardium. The most important index of pericarditis is the pain that usually occurs in the precordium. Another is the tenderness that is usually present whenever there is an effusion into the pericardium. If the rule is made of eliciting dulness in the heart region by reasonably deep percussion, there will usually be at least a suspicion aroused of the presence of pericarditis in all cases where it exists. Almost more important for the diagnosis of pericarditis than palpation of percussion is inspection. If patients are examined in a good light, distinct bulging of the rib interspaces will often be noticed. Besides, there is a wavy impulse communicated to the tissues of the precordium. Unfortunately, however, it is not the custom to examine patients' chests in a good strong light.

There is no pathognomonic sign of pericarditis, but the finding of an apex beat well within the outline of heart dulness is almost pathognomonic. Sometimes it is impossible to feel the heart impulse while the patient is lying on the back. Sometimes such patients are asked to sit up and lean far over. This is an extremely uncomfortable position, besides being a little dangerous if the pericardial effusion is large. It is much better to have the patient turn over into the prone position and then by drawing up the knees assume a limited genupectoral position. In this way palpation and percussion are possible and the heart is thrown forward against the chest wall and the impulse can be easily felt.

DR. H. B. SEARS, Beaver Dam, Wis.—I wish to relate an extreme case of adhesive pericarditis which occurred in the practice of Dr. F. Shimonek and myself. The patient was a member of one of the Wisconsin regiments engaged for some time in the Southern States. While South he suffered from malaria, also had an attack of acute inflammatory rheumatism. On returning to his home in Wisconsin, he began to suffer from dyspnea and impaired digestion. The heart's action became very feeble and irregular, with imperceptible apex beat, showing wave-like motion in intercostal spaces over entire precordia.

The liver gradually enlarged, reaching down to the umbilicus. Ascites, with edema of the lower extremities, supervened and tapping became necessary on account of the dyspnea and general discomforture. He was tapped at intervals of two weeks at first, gradually shortening to five or six days during the last year. The tappings extended through a period of five or six years, giving a total of 283 tappings and about 5000 pounds of fluid removed. A sudden chilling resulted in suppression of urine, uremic coma and death. Postmortem showed pericardium obliterated, myocarditis, with degenerative changes and thinning of heart walls. Heart was adherent to pericardium throughout, also to pleura, diaphragm and sternum, between which and the heart there was a calcareous deposit the size of a tea-plate. It seems a great wonder that the heart continued to act under such extreme bondage. And yet, the patient was about each day, enjoying his pipe, his record of tappings and his daily morning tonic of a half onion for breakfast.

DR. JAMES B. HERRICK, Chicago—Dr. Babcock has referred to the value of the pulsus paradoxus and I agree with him that it is not pathognomonic. Yet, in three cases, two going to autopsy, it seemed to me that this sign was of considerable value from a diagnostic standpoint.

In one of my cases of adherent pericardium there was paralysis of the vocal cord on the left side; this I regarded as due to the recurrent laryngeal nerve becoming involved in the adhesions. At the postmortem it was found that just where the nerve wound about the aorta, it was caught in firm adhesions, and the nerve gave both macroscopic and microscopic evidences of degeneration. There was also some pressure from an enlarged left auricle, for there was present a marked mitral stenosis. Cases of recurrent nerve paralysis due to pressure from an enlarged auricle have been noted by Ortner. Osler also makes reference to a case, and recently at the German Congress of Internal Medicine Kraus reported a case, though he differs as to the explanation of the production of the paralysis.

It is very important that we should examine cases of suspected pericardial effusion behind. The signs in the posterior left chest are often quite striking. Dulness behind, and bronchial breathing may clearly hint at the existence of a pericardial effusion with compression of the lung. So marked may the signs in the axillary and infrascapular regions be that we may be in doubt as to whether there is consolidation or fluid in the pleural cavity, and not a few mistakes have been made by puncturing the left axillary space and obtaining fluid, which at the postmortem was found to have come from the pericardium and not from the pleural cavity.

DR. CARL BECK, New York City—I am sorry that I was not present at the reading of all the papers on this subject. In reference to the differential diagnosis of adherent pericarditis, as spoken of by Dr. Babcock, I should like to call attention to the value of the fluoroscope, which would show the diaphragm in close contact with the pericardium during its excursions. I should like to ask Dr. Babcock as to the advisability, in cases of adherent pericarditis, of approaching the adhesions with the surgeon's knife. We are no longer afraid of the pericardium. I had great pleasure in seeing a boy, a few months ago, recover after opening and draining the pericardial cavity. Just as 25 years ago we were afraid to open the pleural cavity so now do we seem to be afraid to open the pericardial cavity

and, it may be, the work of the surgeon in the treatment of pericardial effusions and their consequences will be somewhat similar to what it has been in pleuritis.

Dr. Frank D. Smythe, Memphis, Tenn.—Pericarditis accompanies the pneumonia in almost every case in the negro; but this is not so in the white. In this connection I should like to bring your notice to some interesting cases under observation during the past year. Three cases were seen in consultation with Dr. Jones; two had an endocarditis, with mitral insufficiency, as a result of gonorrhea; the other was a case of pyocardium referred to me by a neighboring physician as a case of pleurisy with effusion which should be tapped. An examination revealed an enormously enlarged precordial dulness and I called Dr. Jones in consultation. He concurred with the diagnosis. We opened and found pus, withdrawing one-half a pint. This patient slowly improved. Another case was seen in my surgical service; it was one of pyocarditis due to rupture of an abscess of the liver into the pericardium. Shortly after the evacuation of the pus the patient died.

Dr. Robert B. Preble, Chicago—I have of late been particularly interested in symptoms arising from recurrent laryngeal nerve because of their frequency in certain cases of aortic aneurysm; exactly similar symptoms are seen in pericarditis also. The left recurrent laryngeal nerve passes downwards into the thorax, and then curving around the arch of the aorta ascends to the larynx. This brings the nerve into close anatomical relation to the pericardium and symptoms of irritation or of paralysis result. This nerve sends branches, some to the heart—to the cardiac plexus—some to the esophagus, and some to the larynx. When this nerve is irritated, symptoms arising from any one or all of these branches appear. It is not possible to say why in any given case the symptoms are limited to one branch rather than distributed over all; thus we may have esophageal symptoms, laryngeal symptoms or cardiac symptoms like those of the angina pectoris in varying degrees. This explains the dysphagia occasionally seen, although in some cases direct pressure on the esophagus is the cause. I was interested in Dr. Jones' statements regarding the lesions of the aortic valve; they were at variance with the commonly accepted statements. Aortic lesions are generally stated to be less frequent than mitral lesions and I believe that this is true. One must distinguish two forms of aortic insufficiency, one the result of an endocarditis, such as complicates rheumatism, pneumonia, or sepsis; the other form of aortic insufficiency, more common, but less generally recognized, is met with either as a primary inflammation of the aortic valves or secondarily by extension from an inflammation beginning on the aorta, a primary aortitis. Syphilis is a common cause of such primary aortitis, and while syphilitic changes in the smaller arteries are usually delayed for years, the aorta and its valves are frequently affected early. Such syphilitis aortitis is characterized by just the symptoms dwelt upon by Dr. Jones, retrosternal pain, angina pectoris and sudden death, a group of symptoms which are not a part of aortic endocarditis such as occurs complicating the various septic diseases. I believe that the great frequency of syphilis in Dr. Jones' patients accounts fully for the differences between his and the general experience.

Influence of Food on the Re-establishing of the Movements of the Heart.—At the International Congress of Physiology held at Turin in September, Prevost and Batelli reported experiments which demonstrated that dogs could be revived more rapidly and effectually after asphyxiation from ligature of the trachea, if not fasting. Simple massage of the heart was sufficient in most cases to restore the heart action, without artificial respiration, when the dogs had been fed on mixed food, the carbohydrates predominating. Fats proved the least effective in this respect. The respiratory movements first appeared in all the tests after massage of the heart and artificial respiration. Much later the dilated pupil contracted and then in turn the knee-jerk, the corneal and nasal reflexes made their appearance, and lastly the inhibiting reflex of the superior laryngeal.

COMPLETE RECOVERY FROM DOUBLE NEURO-RETINITIS,

CLINICALLY RESEMBLING ALBUMINURIC RETINITIS, IN A CASE OF PROLONGED HEMATURIA WITH SYMPTOMS OF BRIGHT'S DISEASE.*

C. A. VEASEY, A.M., M.D.
PHILADELPHIA.

The notes of the following somewhat unusual case are deemed of sufficient interest to merit their isolated report.

Mrs. C. H. P., aged 35 years, was referred to me in May, 1899, by her physician, Dr. Hassell, for the examination of her eyes. The following history was obtained: Eight months previously she had suddenly discovered that she was passing bloody urine. This had occurred without any pain or premonition whatever, so that she was naturally much startled, and at once sought medical advice. From that time, however, until the time of my examination, urine had been passed upon but few occasions that it did not contain considerable blood. The exact amount of blood could not be accurately determined, but it was sufficient to make the urine a dark red, and quite thick. For several months the patient had been losing flesh (about 20 pounds altogether), and when I first saw her she was quite weak, very pale, suffered from attacks of vertigo, dyspnea, tinnitus aurium and intense constant headache. The lower lids were puffy, and at times there was a slight edema of the legs. She also complained of pain in the back, and physical examination showed moderate cardiac hypertrophy. Her family history was good and her health had been excellent until the appearance of the hematuria. There had been no convulsions, nausea or vomiting, except when the latter accompanied an occasional attack of migraine, of which there was a clear history.

Two weeks before coming to see me she had observed some diminution in the visual acuity, with increase in the vertigo and headache, and greater dyspnea. The vision of the right eye equaled 6/7.5; of the left 6/5. There were no external ocular changes. With the ophthalmoscope the right eye showed a clear media, an oval disc with its edges everywhere veiled, the veins full and slightly tortuous, especially in the immediate neighborhood of the disc above and below where they, as well as the arteries, were covered with exudate. There were five small feathery hemorrhages along the blood vessels in the neighborhood of the disc, and one on the surface of the disc near its outer border. In the macular region was noted the typical whitish stellate figure, so often observed in nephritic lesions.

In the left eye practically similar conditions were found, perhaps a little more marked in the disc and its immediate neighborhood, and slightly less marked in the macular region. The pupil of each eye reacted perfectly, and the fields were slightly contracted both for form and color, but there were no scotomata.

Repeated examinations of the urine showed large quantities of blood corpuscles and albumin. No tube casts were found at any time, but it must be remembered that on account of the great admixture of blood with the urine their detection would have been difficult had they been present. In order to ascertain whether the blood had its origin from the bladder or from the ureters or kidneys, both ureters were catheterized

by Dr. Richard C. Norris, and the urine obtained from each contained blood, though the specimen from one side was somewhat clearer than that from the other. No tubercle bacilli could be found in any specimen.

The examination of the blood showed a uniform moderate reduction of the hemoglobin and red cells, together with a slight increase of the leucocytes—in other words, the conditions usually found in a mild secondary anemia, such as accompanies any wasting disease. The clinical conditions, therefore, were apparently those of an albuminuric retinitis in a patient whose general appearance was that of one suffering from some chronic nephritic lesion, whose urine contained large quantities of blood and albumin, and whose blood presented such changes as are usually found in those affected with some wasting disease.

Recovery was naturally very slow, but under a strict milk diet and the administration of Basham's mixture, and such other drugs as occasion demanded, clear urine was occasionally voided. These periods became more and more frequent, sometimes two or three days passing without any hematuria, the clear urine containing very little albumin, and the patient beginning to gain in weight. Simultaneously the ocular symptoms began to disappear. The small hemorrhages were first absorbed, the swelling of the nerve heads slowly subsided, and the stellate macular figures gradually diminished in intensity, until at the expiration of nine months from the time of my first examination the ophthalmoscope revealed no intra-ocular changes. The nerves were healthy in appearance and normal in color, the edges well defined, the vessels were unchanged and there were no traces of the minute hemorrhages previously noted, the macular regions giving absolutely no indications of the previously existing conditions. Vision in each eye equaled 6/6, and the fields were normal.

From a study of the symptoms and course of the affection the most plausible explanation seems to be that the patient at first had an acute inflammation of the kidneys, which ran into a chronic state, at the expiration of eight months producing the intra-ocular lesions previously described. What bearing the hematuria had upon the condition, whether it was a factor in the production of the nephritis or vice versa, or occurred merely as a coincidence, can only be surmised.

It certainly must be an extremely infrequent occurrence to have neuro-retinal lesions of the character and severity of those above described clear up so thoroughly that not a trace of the former condition can be found. In a paper before the American Ophthalmological Society in 1886, Bull analyzes 103 cases and states that at the time visual improvement was taking place in 32 cases while under constitutional treatment, the retinal changes became perceptibly less marked; but he had never in any case seen any signs of absorption in the peculiar glistening stellate exudation at the macula, and that he did not remember ever to have seen a case in which the retinal exudation was entirely absorbed. In this analysis all cases of albuminuric retinitis due to pregnancy or scarlet fever were excluded, as the retinal lesions in this class of cases had been seen frequently to disappear entirely. On the other hand Leber refers to the absorption of the exudation which takes place in those cases of retinal disease which are cured, or brought to a standstill; and Gowers, in his well-known work on "Medical Ophthalmoscopy," states that occasionally the retrogression may proceed until the retinal changes almost or quite disappear, and that this is especially the case when the affection comes on in the course of the chronic kidney disease which results from an acute attack, in which considerable improvement in the retinal affection is often obtained. It seems that the latter remarks apply particularly well in explanation of the somewhat unusual case here reported.

DISCUSSION.

Dr. William H. Wilder, Chicago—This subject is an extremely interesting one because the general practitioner always wants to know of what prognostic significance this optic sign of albuminuric retinitis is. I think it is pretty generally accepted that when it does appear it almost signs the death warrant of the patient. There are very few cases of typical albuminuric retinitis that are not of grave prognosis, and most of them terminate fatally in about two years. I do not recall that I have ever seen a case run beyond that. I have seen a case, however, that occurred in a patient that I watched very closely where the retinal lesion improved decidedly before the termination of the case in death. The vision had fallen to 5/200 with marked stellate appearances around the macula and with hemorrhages, but the vision improved to 20/40 and remained there until death, with a corresponding diminution of the white plaques and hemorrhages. I have seen a similar appearance in a case of diabetic retinitis. In Dr. Veasey's case I should expect grave developments to occur within a year or so.

Dr. Hiram Woods, Baltimore—My attention was called a year ago to the paper of Marcus Gunn by Dr. de Schweinitz, whom I had asked to see a small boy 9 years old that consulted me because of loss of vision in the right eye. There was marked venous engorgement and small hemorrhages with, starting out from the fovea, a number of white streaks. The case had no albuminuria and eventually got well, except that a small scotoma in the inferior temporal field remained. Gunn described several cases of this kind and believed them due to a certain pegging down of the retina near the fovea, and that the white streaks were exudative, but not of a degenerative character found in albuminuric cases.

Dr. E. C. Ellett, Memphis—I would like to mention briefly a case of what might be almost termed recovery from albuminuric retinitis. The patient was a young woman whose Bright's disease lasted over a period of fifteen years. Within two or three years of the probable onset of this she developed a typical albuminuric retinitis. There was no ocular treatment, but under the care of her attendant the condition became very much better and the ocular condition passed into what might be called atrophy of the retina, that is, there was a very marked thinning of the retinal vessels, almost an obliteration, but the condition of the nerve was good and the central vision became very good, although the field was contracted. A case almost identical with this, following an albuminuric retinitis of pregnancy, was seen in Dr. Jackson's service at the Will's Eye Hospital about ten years ago, when I was resident surgeon there. The subsequent history of my case was that the patient died, but without any recrudescence of the eye symptoms.

Dr. C. A. Veasey, Philadelphia—The case referred to by Dr. Woods could hardly be mistaken for this condition, because in that class of cases the swelling is in the character of lines more than in blotches and there is not the typical stellate figure nor albumin in the urine. I can not say that the condition was due to kidney disease, as nothing short of an autopsy will show that; but I believe it was a case beginning as an acute nephritis, becoming chronic and later setting up those retinal conditions which have been described by Leber and others.

Soluble Bougies for Treating the Lachrymal Duct.—Steinitz uses a 1 to 5 per cent. protargol, or a 1 per cent. colloid silver, soluble bougie in the treatment of rebellious cases of suppuration of the lachrymal duct. He has been very much pleased with the result in six cases rapidly cured by this means, as he describes in the *Klin. Monatsblaetter f. Augenheilkunde*, 1900, p. 343.

THE VALUE OF EXCISION OF THE SUPERIOR CERVICAL SYMPATHETIC GANGLION IN GLAUCOMA.*

GEORGE F. SUKER, M.D.

Professor of Clinical Ophthalmology, Post-Graduate Medical School; Clinical Instructor in Ophthalmology in College of Physicians and Surgeons.

CHICAGO.

The history and modus operandi of this operation, as well as its intended and desired range of purpose, are all familiar to you, hence these points do not merit repetition here.

In order to obtain as complete American statistics as possible, the writer has sent out several hundred question blanks to men of repute and experience. However, the returns are a trifle meager, yet of such great importance on account of their uniformity, that a fair and just estimate may be had as to the real merits of the operation in question. There have been only 14 operations performed in America for glaucoma; in addition, several have been done for optic atrophy and Basedow's disease. If there are any more operations for glaucoma the writer has failed to get the report, though every effort was made to obtain same.

First, let us take a brief review of the physiology of the superior cervical sympathetic ganglion and nerve with reference to the eye. It supplies: 1, the iris with dilating fibers; 2, the blood vessels of the eye with vasomotor fibers; 3, the unstriated muscle of Tenon's capsule; 4, the trophic and nutrition fibers of the globe proper; 5, the lymphatic vessels and channels are under the immediate control of the sympathetic fibers.

Any constant or interrupted irritation of this ganglion or its fibers gives rise to: 1, vaso-constriction; 2, circumbulbar muscle contraction; 3, an increase in the elements of the aqueous humor, hence an active interference with the intra-ocular interchange of fluids; 4, a dilatation of the iris, therefore an interference of the filtration angle; 5, finally, an increased intra-ocular tension.

Now, what takes place when this ganglion is removed? 1, contraction of the iris; 2, relaxation of the circumbulbar muscle; 3, vascular dilatation; 4, lower intra-ocular tension; 5, a decrease in the elements constituting the aqueous.

These points have all been proven by experiment many a time, hence beyond any question of doubt.

If these facts hold true for a normal eye, then the same results obtained, if possible, in any form of glaucoma ought to be productive of good; and, what is more, the extirpation of this ganglion, if the foregoing facts are absolutely true, is in certain forms of glaucoma the only permissible operation of to-day. This, for the reason that it prevents enucleation of the globe in glaucoma absolutum and possibly hemorrhagicum.

In every instance of glaucoma the extirpation of this ganglion has achieved some good, though the results have been more or less permanent. Yet the good of this operation has not impressed itself upon operators at large.

A certain element of doubt always attends the removal of this ganglion. To absolutely recognize the ganglion or its fibers is often a matter of great difficulty. The ganglion may vary greatly as to position, size, shape, color and texture; and, unless one is familiar with its so-called eccentricities he is not absolutely sure of having removed it. However, if you apply the galvanic or faradic current and watch its action upon the iris, which is well known, you can not go astray. This one difficulty may have been the reason for a failure in some cases. No less an authority than Byron Robinson says: "The sympathetic ganglia of the neck are very perplexing, to say the least. The only way to become familiar with these ganglia is to hunt for them in the anatomical room."

The superior cervical sympathetic ganglion, as well as the middle, has been removed for epilepsy, Basedow's disease, optic atrophy and trifacial neuralgia. These operations have been mostly performed by foreign surgeons. Yet, the experience and the careful study of the data will go to show that the sphere of this operation is limited to glaucoma and Basedow's disease. It is of doubtful utility in trifacial neuralgia, even if reported by Jaboulay. The experience of such men as Angelucci, Coover, Black, Burghard, Ball, Dodd, Williams, Jonnesco, Demicheri, are the warrant for the foregoing statement.

The true etiology and pathology of any variety of glaucoma can never be established unless the sympathetic cervical ganglion and the lenticular ganglion are taken into consideration. Nor can any cure for glaucoma be advanced in the future unless these ganglia are reckoned with. Perhaps another Sterling will unravel the problems as to the pathology of these organs.

Before giving an analytical review of the statistics the writer has gathered, he wishes to offer the following as the probable cause for the failure of sympathetectomy in certain forms of glaucoma. This cause he thinks is in the overlooking of the lenticular ganglion. Judging from its makeup, position and function, it must play an important part whenever the sympathetic nerves of the eye are in question. This ganglion supplies all the nerves of the intrinsic eye muscles—both motor, sympathetic and sensory. It receives sympathetic filaments directly from the superior sympathetic ganglion as well as crossed branches of the sympathetic fibers which accompany the branches of the fifth nerve to this ganglion. The excision of the cervical ganglion then leaves intact the sympathetic fibers coming with the fifth nerve to the ciliary ganglion. The questions which the writer puts to himself and which form the basis of experiments now being carried on, are:

1. What is the effect on the eye when you stimulate the lenticular ganglion after the removal of the superior cervical sympathetic?

2. What is the effect when both ganglia are removed?

3. What is the effect upon the eye after the removal of the superior cervical sympathetic ganglion, section of the third and fifth nerves intra-cranially and the stimulation of the lenticular ganglion?

If these experiments yield any positive data, then the rationale of the operation in question will be strengthened and we can arrive at a more logical conclusion as to its real value.

In studying the statistics, only the salient questions will be taken up. In answer to the question, "For what forms of glaucoma did you operate?" the following was received: Chronic simple glaucoma, 9; glaucoma absolutum, 3; sub-acute glaucoma, 1; hemorrhagic glaucoma, 1; total, 14.

Of these operations two were bilateral, thus leaving twelve individual cases. Briefly, now, as to the success of these twelve individual cases as given by the respec-

*Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

tive operators we have: Success, 6; improvement (ending in failure), 3; failures, 3.

This certainly is a good showing, especially when two failures are not to be considered. For, in one case the diagnosis lay between optic atrophy and glaucoma—balance in favor of optic atrophy. In the other, such atrophic changes had already taken place that the case was a desperate one from the start, though a temporary improvement followed the operation. Such is the opinion of the respective operators in each of the cases just mentioned. Furthermore, the record of success is good in that it prevented enucleation in three cases of glaucoma absolutum. Thus, deducting the two cases above detailed as failures, we have six successes and four failures in a series of ten cases—counting the double excision as a single operation.

For the next question of importance, "For which forms of glaucoma do you advocate the operation?" the reply was: 1, hemorrhagic glaucoma; 2, glaucoma simplex; 3, glaucoma absolutum.

In the hemorrhagic and absolute forms of glaucoma the operation prevented enucleation and removed pain, hence a justifiable procedure. In the chronic forms of glaucoma it was done after an iridectomy had failed to relieve the downward tendency of the glaucoma. Yet, the greatest percentage of failures comes from this class of glaucoma. In a few cases only did the extirpation of the ganglia in chronic glaucoma suffice, as in the majority a subsequent iridectomy had to be made. Therefore, as far as this variety of glaucoma is concerned, it must be held *sub judice.*

In considering the immediate effects of the operation, i. e., within 24 to 48 hours, the report gave the following: 1, marked reduction of tension in each individual case; 2, immediate contraction of pupil; 3, immediate relief from pain if same was present prior to operation.

On these three points there was no variance. The only condition which varied was the improvement of vision. In a few the acuity and field of vision was greatly improved, but the greater majority retained about the same amount of vision as prior to the operation—excepting the recorded failures, in which, though, there was a temporary gain.

In only one case was the reduction of tension delayed longer than 48 hours. Then in one case a previous double iridectomy prevented pupillary manifestations, i. e., maximum contraction. However, there is a great uniformity of results, as can be noted from the remarks made.

The next important question was: "Can it replace iridectomy or sclerotomy?" To this all gave a very guarded answer, which is perfectly correct. For the enthusiastic feature of the operation has passed away and bare facts are at hand. Yet each operator looked upon the operation as worth trying when other procedures failed.

As to the acuity of vision, the results again are similar. In Ball's case, e. g., the vision rose from light perception to counting of fingers at seven feet in 32 days; in the other from light perception to fingers at four feet within three months; in the third from nil to fingers at four inches, the time not given, however.

Coover, in his case of glaucoma simplex, reports a decided gain in vision lasting four months, with a subsequent failure. He admits, however, that his case was a desperate one from the beginning.

Mullen, of Houston, Texas, reports an increase in the field of vision in his case of non-inflammatory glaucoma, though finally it receded to a point the same as before the operation.

Melville Black, of Denver, likewise reports a decided increase of vision in his case of subacute glaucoma.

In Gradle's case of chronic glaucoma, in which a double iridectomy had been made, though it failed to check the downward progress in one eye, the excision of the ganglion retained the same field of vision for at least fifteen months, and this eye is apparently better than the other now.

Huizinga's case was not a clear-cut glaucoma, but rather an optic atrophy, hence his negative result can not be considered. This is what he himself reports. In the writer's two cases of chronic glaucoma the acuity of vision was not improved, but the same amount was retained as was present prior to the operation; the time elapsed is about two and one-half years for each case.

The excision of the ganglion twice prevented an enucleation in glaucoma absolutum for the writer, and Ball also reports a case where it obviated an enucleation. So we can see from these three cases that the operation has a sound basis for this form.

In none of the reported cases was any after-treatment, i. e., medicinal, employed, so the real value of the operation is brought to light. However, it seems more rational and more in accordance with the views of operators to follow up the operation with myotics for at least a certain length of time, if not continually.

There is no question but that the amount of success depends in a certain measure upon the stage of the disease. If there is no central vision or even light perception, not much in the way of visual improvement can be hoped for, though the other existing symptoms are surely allayed. As to the untoward effects following the excision, none have been reported. Yet there are some, such as flushing of the face on the same side, dysphagia and slight ptosis. These after-effects, however, are only temporary. With this rather hasty review of the subject as it stands before you, permit the writer to give a summing up of the most pertinent facts:

1. Sympathetectomy is a justifiable operation.
2. Though the excised ganglion shows changes, yet the true relationship between it and glaucoma is an open question.
3. It is not the *sine qua non,* but a most valuable adjunctive procedure.
4. It is always indicated when an iridectomy or sclerotomy in any form of glaucoma has failed.
5. Iridectomy is still the classical treatment for certain forms of glaucoma, i. e., chronic and acute.
6. It is the preferable procedure in glaucoma absolutum and hemorrhagicum.
7. Operate only on one side—affected side.
8. Employ the suitable medicinal treatment after the operation.
9. Do not extirpate the ganglion in acute inflammatory forms of glaucoma.
10. There probably is a close connection between the ciliary, superior cervical sympathetic and glaucoma. What it is, experiments will show.
11. Extirpation of the ganglion is indicated whenever there is increased tension not controlled by any other measure.
12. The results depend in a great measure upon the condition of the case.
13. Primary extirpation may have to be followed by an iridectomy.
14. It is indicated in those cases of glaucoma which already have extremely poor vision and where any interference with the eye proper might result unfavorably.

15. It is to be considered at all times when other operative measures are refused, irrespective of the form of glaucoma.

16. The excision of this ganglion has varying effects upon the fundus oculi—none detrimental, however.

The writer having been a very great enthusiast concerning the value and future of sympathetectomy in nearly all forms of glaucoma, has, after three years of close study, experiment and following up his cases, been compelled to give the foregoing conclusions, which certainly are very conservative. To think that it will ever entirely supplant other operative procedures in glaucoma is a question and could not receive the support of him who is at all an acute observer.

The following is the list of operators and the number of their cases irrespective as to the form of glaucoma: Ball of St. Louis, 3; Coover of Denver, 1; Black of Denver, 1; Huizinga of Chicago, 1; Gradle of Chicago, 1; Mullen of Houston, Texas, 1; Suker of Chicago, 4. The double operations are counted as single cases.

In conclusion, the writer wishes to express his gratitude to Drs. Ball of St. Louis, Coover and Black of Denver, Mullen of Houston, Texas, Huizinga and Gradle of Chicago, whose cases have formed the basis of this paper.

100 State Street.

DISCUSSION.

DR. CASEY WOOD, Chicago—It is only fair for me to say at the outset that I have not had a case myself in which the superior cervical ganglion has been removed; I was merely called in consultation in a case with Dr. Huizinga. Those of us who approach this matter in a conservative fashion have the right to ask certain questions. First, is the operation a dangerous one? If so we must not compare it with the simpler operation of iridectomy and give it the same importance and prominence. If there is any procedure or remedy in acute or subacute glaucomas I believe it is an iridectomy done in the sclera with removal of a wide segment of iris. I do not think we should be justified in resorting to an operation of a kind which can only be done by an expert surgeon, requiring special skill where a simpler one, devoid of risk, will probably be as effective. As to the chronic form of glaucoma I am one of those who think that many of the cases are not pathologically kin to acute glaucoma. I believe that we often have to deal with an optic nerve trophy associated with physiologic cupping. Of course there are two camps fighting each other on this subject, but I am certain the case I saw with Dr. Huizinga is one of that kind, and that, consequently, one had no right to expect a brilliant result from the operation and, as a matter of fact, we did not get it.

DR. MELVILLE BLACK, Denver—I should be inclined to say that the operation of sympathectomy is not a difficult one in the hands of a skilful surgeon or even in the hands of an oculist who has seen it done a few times. There is no special danger connected with the operation if the operator knows his anatomy. My case was one of subacute glaucoma in a negro, 35 years of age. The superior and middle cervical ganglia were removed. The man was rendered myopic by the operation temporarily. The pupil contracted down to the size of a pin's head and the symptoms absolutely subsided at once. Up to the present there has been no return of the symptoms of glaucoma, and that eye is equally as good as the other. The operation was done December 24, 1900, and the time has not been sufficient to determine what its ultimate results will be; the one case does not make me think it is going to take the place of iridectomy. Still, if I had glaucoma I should prefer to first have the ganglion removed to having an iridectomy done. I think the operation only has its place where eserin will reduce the tension and improve the vision.

DR. WILLIAM H. WILDER, Chicago—I am scarcely prepared to give a report as yet on the case which is under observation in my service at the infirmary. During the last year my colleagues and myself have had three cases, one done in the service of Dr. Fisher, one in that of Dr. Woodruff, and the one I have recently done. The results were very gratifying in the case of Dr. Woodruff. On the first examination the field was slightly improved, not only for white but for colors. In my own case the vision has improved from 20/70 to 20/50; the tension is normal and the pupil, which returned to normal size, responds readily to light. It is difficult to pass judgment on an operation the statistics of which are so meager, but possibly there is a field for this operation. I can hardly agree with Dr. Black that it is a simple operation. It may be simple on the cadaver, but almost a nightmare confronts one when one gets to cutting back of the large vessels in the neck. I was glad to have Dr. Schaeffer assume the responsibility of operating in my case. The operation appeared simple enough in his hands, but I should not like to attempt it without going over the topographical anatomy quite frequently.

DR. C. F. CLARK, Columbus—What symptoms in other organs have developed after this operation?

DR. SUKER, in reply—We have a flushing of the face on the side operated on and there is a possibility of having an enophthalmos which is persistent.

REPORT OF A CASE OF A PECULIAR FORM OF CARCINOMA OF THE SKIN OF SLOW GROWTH.*

WILLIAM FRICK, A.M., M.D.

Lecturer on Clinical Dermatology, Kansas City Medical College, and to Kansas City Training School for Nurses; Dermatologist to Kansas City, Fort Scott and Memphis R.R.

KANSAS CITY, MO.

We can conceive of several conditions under which a carcinomatous tumor of the skin may have a history of long duration. A growth may be innocent in its character in the early history of its development, and change after many years of duration to a carcinomatous type. A known epithelioma may remain stationary, or nearly so, for years, apparently neither increasing nor decreasing, after which it increases more rapidly; this will give a long history to the tumor. Then again, carcinomatous cells may be encapsulated, according to some observers, which may prevent their extension for many years. The case we have to report had a duration of 35 years, and did not present the usual appearance of a carcinoma either clinically or microscopically. The patient was seen by a large number of medical men, some of whom were skilled diagnosticians, and yet no one hazarded a diagnosis of carcinoma from the clinical history and appearance. Hence, I think that it is of sufficient importance to warrant its report.

I first saw this patient in January, 1896, and have seen him at various intervals since that time. The only difference in appearance in the five years is in an extension of the growth. This extension has been extremely slow, but perhaps not quite so slow in the last year as in the previous four. The patient is now 54 years old, and has been from his early manhood a periodical drinker. His sprees last from two or three days to as many weeks; while the periods free from drink are from two or three weeks to a year. He seems quite well preserved for a man with such habits. During his sprees the tumor fills with blood to a greater extent than usual, and is followed with more or less breaking down of the tumor tissue. As his wife expresses it: "The sore always looks worse when he is on a spree."

Family History.—Father died of dysentery at 77 years of age, after three weeks of illness. Mother died

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee of the Section: W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

of consumption when 35 years of age. Her disease was contracted 8 or 10 years before death. He had 4 brothers, 3 of whom are living and well; 1 was scrofulous and died in childhood. He had 2 sisters, one of whom is living and healthy; 1 died of quick consumption when 15 years old, after an illness of one year; but only one week in bed. No other relatives had consumption.

History of the Tumor.—About 35 years ago the patient first observed it on the back, between the shoulder blades and just to the right of the spine. It was then about the size of an ordinary pea; elevated above the surrounding skin, and nearly the color of a ripe strawberry. It grew gradually, but very slowly, and did not ulcerate or break the epidermal covering for the first fifteen years of its existence. At that time the growth was no larger than a five-cent piece. The skin was at that time broken, leaving an elevated raw looking surface, which had very much the appearance of spurious granulation tissue, and it bled quite freely. The growth continued to increase very slowly. There seemed to be a constant attempt on the part of nature to heal, which resulted in a partial covering of epithelium in very thin

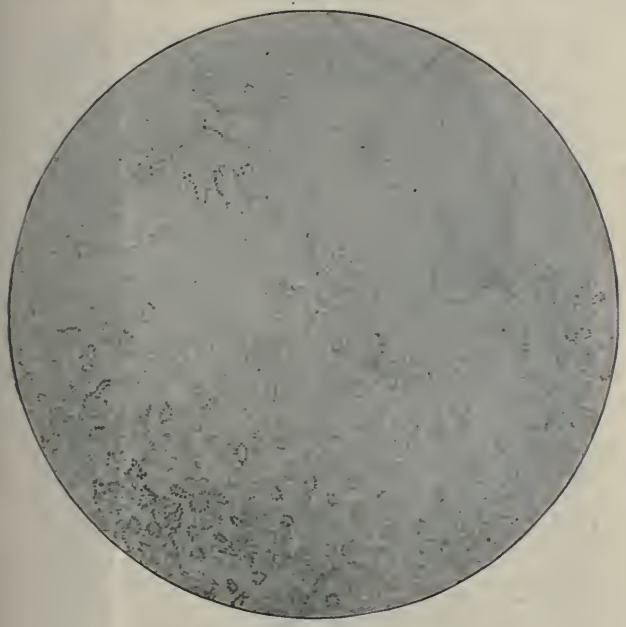

Figure 1.

layers; this was over only part of the growth at a time. Beneath this thin covering could be plainly seen very fine blood-vessels, branching out in various directions. The entire growth was full of blood, and the slightest touch was sufficient to cause bleeding. The tissue making up the mass was quite friable and could be easily scraped out. There was no subjective sensation in the growth. The history given me by the patient and his wife, as well as my observation of it for the last five years, would indicate that the character of the growth has not changed since ulcerative processes were begun at least.

The shape of the tumor was irregularly oval and measured 2½ by 3 inches in diameter. It was elevated about ⅛ inch above the surrounding skin, and its edges terminated abruptly. It was quite movable with the skin, free from induration, solitary and painless. About a third of it had no epidermal covering, but looked more like large spurious granulation tissue than anything else. Another third had a very thin covering of epithelium with the tiny blood-vessels quite apparent just beneath, while the remaining portion had a thicker epithelial covering with no blood-vessels visible, but a thin skin resembling the normal, with the pathologic tissue beneath. These different portions can be seen in the photograph upon close inspection.

A small piece was excised from the lower edge of the growth for microscopic examination. This was sent for examination to Dr. Frank J. Hall, who has charge of the

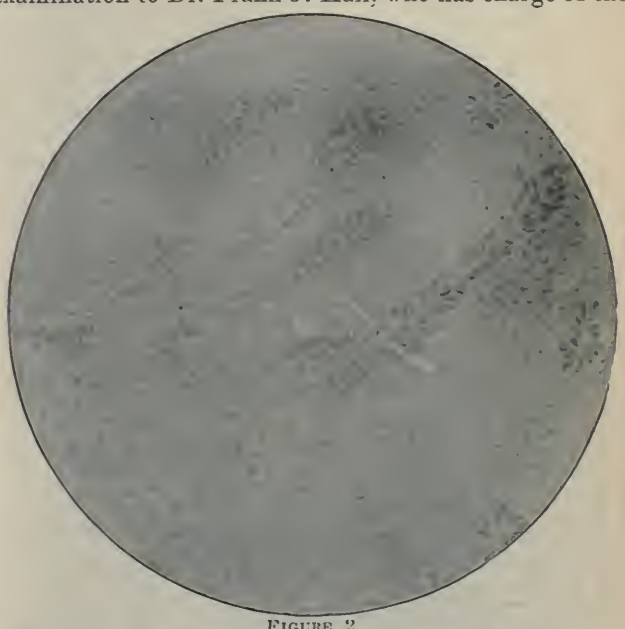

Figure 2.

pathologic laboratory of the Kansas City Medical College. To him is due the credit of ascertaining the histology of the growth.

The excised portion was hardened in 4 per cent. formalin and embedded in celloidin. It was cut thirty micra thick, stained with Delafield's hematoxylin, counter-stained with eosin, and mounted.

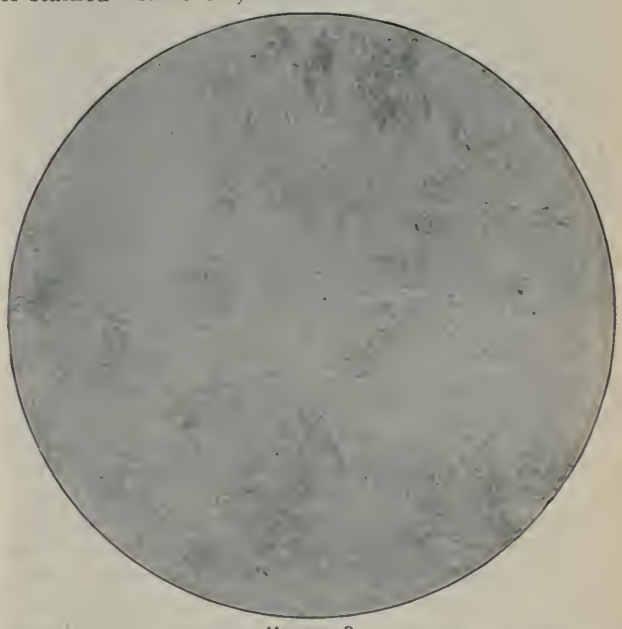

Figure 3.

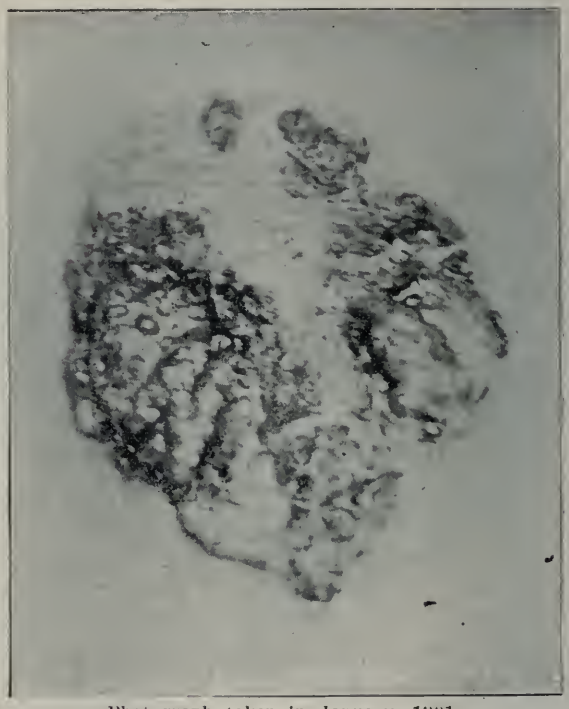
Microscopic Appearances.—With a magnifying power of fifty diameters, the tissue is seen to be made up of closely assembled, irregularly shaped masses of deep stained cells, separated by a poorly nucleated but richly vascular stroma. The cells composing the masses were short spindles, with a very scanty protoplasm and homogeneously staining nuclei. The nucleolus was not of the

vesicular character, so prominent in the epithelial cells of typical carcinoma. No nucleolus was observable in any of the cells examined. All in all these cells resembled more closely the cells of the first or cylindrical cell layer of the stratum Malpighii. Some of these cell masses show a peculiar space in their centers filled with some amorphous matter which retains the hematoxylon. These spaces remind one most strongly of a lumen rather than areas of necrosis, since the cells surrounding these spaces are in a perfect state of preservation. The masses of cells containing these central spaces occupy the deepest portion of the tumor. In no instance is there any evidence of even an attempt at cornification or other degenerative process to be found. All the cells in these masses are practically of the same size, and have their nuclei approximating a vertical position to the peripheral line. The basement membrane, if there be such, surrounding these cellular areas, is extremely poorly developed. An examination of the specimen, including



Photograph taken in January, 1896.

the skin surface at the edge of the tumor, reveals some interesting points. The surface epithelium is well developed, the papillæ are very long and seem to have a tendency to assume a position parallel to the surface of the epithelium. This is shown by the fact that in sections cut vertically a great many papillæ are cut transversely, the interpapillary epithelium being reduced to two or three rows of cylindrical cells. In a few places the interpapillary epithelium was seen to project downward in the form of a very slender column, and to communicate with the cell masses constituting the tumor. Hence we conclude that this tumor has its origin in the epidermis and that furthermore the cylindrical cells alone proliferate. This feature sharply separates this tumor from the ordinary cutaneous epithelioma, since in the latter we find all the layers of the epidermis represented. It is also noticed that sweat glands projecting among the epithelial masses showed no signs of participating in the tumor formation. Sebaceous glands were not observed. Hair follicles were atrophied. We believe that this case is one quite similar to, if not identical with, those described by Krompecher,[1] as "Carcinoma Epitheliale adinoides." It is probably the same growth, described by Brooke,[2] as "epithelioma adinoides cysticum," and by Fordyce,[3] as "multiple benign cystic epithelioma." In all these, except Krompecher's paper, the finer structures at least are not sufficiently described to be sure of the identity of this case with theirs.

One photograph was taken in January, 1896, the other January, 1901.

The three figures illustrating the arrangement of the cells were drawn for me by Dr. W. H. Trimble, associate in pathology in the Kansas City Medical College. Fig. 1 shows the appearance of the cell arrangement at the edge of the tumor under low power. Fig. 2 shows a portion of the same as Fig. 1, under high magnification. Fig. 3 shows a field nearer the center of the tumor.

Treatment.—The patient refused to have the growth excised, and therefore an arsenical paste was used to destroy it. We used the following paste:

Photograph taken in January, 1901.

℞. Ac. arsenious ..... gr. vi
Hydrarg. sulphurat rub. ..... ℥ii
Cocain hydrochlor. ..... gr. i
Ung. rosæ ..... ℥ss
Ft. paste.

This was spread on cloth and applied to the growth each day for four days in succession, after which the destroyed tissue was given time to slough. There was still a considerable part of the growth not destroyed and we used a pyrogallic acid ointment next (℥ss to Ung. Rosac ℥i). This gave more pain than the paste, and did not destroy the pathologic tissue as well, so after a few days we returned to the former treatment. This was used four successive days again, and then allowed to slough. There was still some of the growth to be seen, and another four applications were made, after

which we seemed to have a clean ulcer ready to heal. Healing took place rapidly. The surface formerly covered by the tumor is now covered by soft cicatricial tissue. It will be watched with a great deal of interest for some time to see if the growth will recur.

301 Rialto Building.

DISCUSSION.

Dr. M. L. Heidingsfeld, Cincinnati—Judging from the appearance of the drawings, and they bear evidence of having been carefully and well executed, I am impressed that this case in question is not a true epithelioma. There is some down-growth of the epithelium, but a good wall of connective tissue separates it from the underlying structures; the lowest layer of columnar cells are well preserved, and perfectly arranged; there is no marked hypertrophy on the part of the sweat and sebaceous glands. In fact, we have none of the characteristic ear-marks of an epithelioma, and inasmuch as nearly all the essential features of this form of new-growth are lacking, I would deem it proper to be somewhat guarded as to whether this case can be classed with the epitheliomas.

Dr. H. G. Anthony, Chicago—Clinically, this might be classed as blastomycetic dermatitis. I do not wish to be understood as saying that this is a case of that kind; the histological structure does not quite suggest that, but what I say is simply this: That where a case clinically suggests blastomycosis, mention should be made of the fact that the tumor has been examined for blastomyces.

Dr. William Frick, Kansas City, in closing—Of course, being a case of mine, I am very much interested in it, and I reported it because it was not an ordinary picture of epithelioma. In fact, I do not wish to call it an epithelioma; we called it a carcinoma of a peculiar type, a proliferation of the lower layer of these cells. It certainly is not like an ordinary epithelioma.

RHINOSCLEROMA.*

CHARLES W. ALLEN, M.D.

Professor of Dermatology at the New York Post-Graduate Medical School, etc.

NEW YORK CITY.

My intention is merely to report two cases of rhinoscleroma which have come under by observation, because of the great rarity of the affection in this country, and also because of an unusual clinical course pursued by the first one.

Mrs. L. M., 64 years of age, was born in Hungary. She was first seen in 1889, when the diagnosis of rhinoscleroma was made from the clinical appearances and history. An attempt by Dr. Lustgarten to confirm the writer's opinion through a bacteriologic culture failed. No tissue was allowed to be excised for microscopic examination. At this time an operation was advised as the only means of arresting the progress of the disease. The incurability by drug medication was pointed out, as well as the probability that the growth would soon reach an inoperable stage. The patient, however, would not entertain the suggestion of an operation. The appearances presented at that time are shown in Fig. 1 of the accompanying illustrations. The history given was, that for sixteen years a nodule, the size of a small bean, had been present in the upper lip midway between the vermilion border and the nasal orifice. There was never any pain, and no treatment had been instituted.

Two years before the patient came under my observation the nodule began to increase in size, especially toward the nose, and by a gradual growth invaded the cavity of the left nostril, pushing up the ala. The growth occupied the whole thickness of the lip and extended from just above the vermilion border to well within both nostrils. Beyond the portion which is raised above the *niveau*, there is, as it were, a subdermic, firm plate which can be distinctly felt passing to the right and left. Toward the left, it extended to the labio-nasal fold and on the right, not quite so far. The complexion is sallow, often yellowish, and the general health is not always good; she suffered with frequent headaches and indigestion. The appearances at this time are shown in this photograph taken for me by Dr. Piffard, I think in 1890. I reported the case and showed this photograph (Fig. 1) at the New York Dermatological Society in 1892. Since the patient's history has been so well given by Dr. Jackson,[1] I will not consume more time in dwelling upon it. I show

Fig. 1.—Rhinoscleroma, first seen in December, 1889.

you now this excellent colored drawing which accompanied his article (Fig. 2), illustrating the changes which had occurred up to this time. Dr. Politzer saw the case in 1891. Since this time the patient has been at various times under my care and about three years ago I had the picture made which I now show (Fig. 3). The period between these two last pictures is about five years.

During the past three years the progress has been more rapid. On Dec. 9, 1899, I was called to see her, and found that the growth had increased considerably since the last picture was made, the central portion was of a dark bluish-red color, and occupied by an ulcerating area. There was some fever, general malaise, lack of appetite and considerable local pain. Within the fortnight this whole central mass, including the

1. Jour. Cutaneous and G.-U. Dis., Oct., 1893.

soft gum and under surface of the nose, broke down in a gangrenous slough and was cast off, leaving denuded the bones of the upper jaw and nasal septum. For a

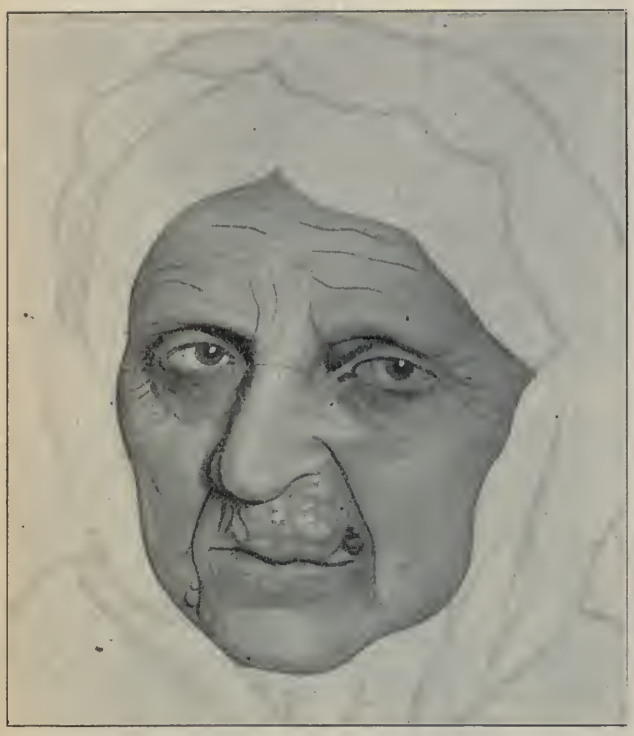

Figure 2.

time the general condition of the patient was such that an unfavorable prognosis as to her life was made. On April 15, I saw the patient last; the exposed bones

Fig. 3.—Rhinoscleroma.

had then become wholly covered with neoplastic tissue of waxy appearance, in all probability of the same nature as the original tumor.

The patient now, for the first time in my observation of her case, extending over eleven years, desired an operation for cosmetic effect. The reason for this will be better appreciated by looking at the painting which shows the condition as it was about two months ago (Fig. 4). As may be seen, however, any surgical procedure of a radical nature is out of the question.

The other case, which is illustrated in the photographs, is also one upon which a previous report has been made, so I need not go into the history in detail.

The patient, I. T., male, aged 49, a native of Galicia, came to me about three months ago. His breathing through a tracheotomy tube, which he has been compelled to wear since 1891, was labored; he was weak and emaciated, and only able to walk a few blocks from home. Speaking only in a whisper and very indistinctly his history was obtained with difficulty.

Nineteen years ago he had noticed a small growth

Fig. 4.—Sloughing in rhinoscleroma.

upon the right side of the nose, the size of the tip of his little finger. For thirteen years, he says, this swelling remained almost stationary and gave no inconvenience.

In 1891, however, which appears to be, according to his story, three years before there was marked increase in the size of the nose, he passed ten weeks in the Mount Sinai Hospital on account of "asthma," and here a tracheotomy was done. This difficult breathing dates back a number of years. Six years ago patient says he was injured on a street railway, and from this date the nasal growth made rapid headway. The present dimensions and appearances are better appreciated from the accompanying photographs (Fig. 5) than from any description I could give. The nares are almost totally occluded. The skin surface is studded with horny and sebaceous plugs of great size, penetrating deeply into the tissues between greatly dilated veins. The color is for the most part a dusky

brownish-red. At times there appears to be an increased congestion.

The appearance of the pharynx and fauces is striking. The uvula is absent and at its site is a round opening,

Fig. 5.—Rhinoscleroma.

which would admit a quill into the nasal pharynx. This latter is otherwise shut off by longitudinal bands of glistening, firm cicatricial tissue. Similar bands

Fig. 5.—Rhinoscleroma.

occupy the lateral aspect of the fauces, giving an appearance somewhat like the opened gills of a fish.

I began treatment with a general tonic course and then gave potassium iodid, but stopped the latter after several attempts, the patient seeming to possess an idiosynerasy against it. There has been some general but no local improvement.

Fig. 5.—Rhinoscleroma.

It was only after my paper was finished to this point that I learned that this patient's history had already been written, and I have since received, through the

Fig. 5.—Rhinoscleroma.

courtesy of Dr. W. Freudenthal, New York, a copy of his excellent report.[2] I refer to this paper for fuller clinical history. I think, however, that it is well to keep track of these cases and report upon their subsequent course.

2. N. Y. Med. Jour., Feb. 1, 1896.

In Case 1, it is not without interest to note the retrogressive changes, especially in view of the statement so often made by writers that the disease shows no tendency to break down. Jackson says, "The course is without tendency to ulceration or softening." Winfield says, "Tumors never suppurate except as a result of improper or meddlesome treatment." Unna, in his "Histopathology," says, "It is entirely painless and shows absolutely no tendency to spontaneous breaking down." On the other hand, Zeissl[3] has reported an instance in which a considerable portion of the nose broke down in an ulcerative process. The long duration of the process of evolution is well illustrated in both cases.

I would not propose changing a clinical name now so well established, despite its inadequacy to describe the whole condition. A name to do this would have to be something like rhino-labio-palato-orbito-pharyngo laryngo-scleroma, and even then it would not cover every case. It seems, however, to be stretching a point to call the affection rhinoscleroma during the years which may intervene between the time of onset in some mucous membrane, or in the throat and the appearance of clinical signs upon the nose. The term gliioscleroma might be more generally appropriate. Kaposi has already used this term, calling the affection granulation sarcoma.

It is probably to be regarded as an infective granuloma of bacillary origin. In the last case Von Frisch's capsule bacillus was found in abundance and cultivated. Its similarity to Friedländer's pneumo-bacillus is striking, as several observers have pointed out. It is from its description, 5 microns long and 2 microns broad, and occurs singly or in groups within cell protoplasm. A Mikulicz cell, which a recent writer, Marschalk, regards as a specific element of connective tissue origin and the result of a special degeneration caused by their presence may contain bacilli in large number.

DISCUSSION.

DR. J. NEVINS HYDE, Chicago—I have seen rhinoscleroma only in Vienna, never in this country.

DR. D. LIEBERTHAL, Chicago—I have seen a case of rhinoscleroma in Chicago and I am keeping track of it. He is not an American, but hails from Moravia, a territory included in the Slav belt, where this disease occurs.

DR. L. E. SCHMIDT, Chicago—The reason we see so little of rhinoscleroma is probably because a large number of the cases go to men who treat diseases of the nose and throat. I know that this is true in Vienna, as I saw many cases in Stoerk's clinic. Furthermore, Kaposi has frequently made the same remark.

DR. C. W. ALLEN, in reply—In answer to the question I would say that I do not remember having seen anything in the literature bearing upon the etiology, but we regard the disease as one caused by a bacillus. There have been some inoculation experiments, usually negative except one where the culture bacillus was inoculated in the eye and a growth occurred which seemed to be of the same general nature and was regarded as a positive finding, but until it is reproduced in the human being I suppose we can not accept it as absolute proof. Being a disease of such long duration it is probably a disease of long incubation and probably it exists as a very slight affection for many years. So we have the same difficulty in tracing the origin as we do in leprosy. We never have had, so far as I know from the literature, any instance of the disease occurring in two members of a family, where it would point to contagion or infection, and there has never been anything pointing to heredity, so far as I know.

THE ROLE OF THE MAST-CELLS IN ACUTE AND CHRONIC INFECTIONS.*

HERBERT U. WILLIAMS, M.D.

BUFFALO, N. Y.

In discussing the relation of the mast-cells to infections, it will be proper first to consider what knowledge we have of their composition and their various properties that may have a bearing on this question.

It has been maintained that their granules are composed of mucin, on the ground that the metachromism displayed by these granules with thionin and other dyes is similar to that shown by mucin. This seems to be the principal argument for the theory, although some also state that mast-cells are numerous in mucous membranes during catarrhs and in tumors containing mucin.

In the writer's experience, while the mast-cells may be abundant in inflamed mucous membranes, they are few or wanting in tumors containing mucin and in the umbilical cord. They may be much increased in structures where mucin seems scanty, as in scirrhous carcinoma. However, since chemists state that there are certainly a number of varieties of mucin, the granules of mast-cells could not be expected to conform to the staining reactions of all mucins.

Variations in the number and size of the granules are common. The writer has twice seen relatively enormous granules, once in the wall of the fallopian tube in pyosalpinx, once in hypertrophic rhinitis.

What undoubtedly appear like granules free in the tissues are often observed. They may be only sections of the long and sinuous processes which many of these cells possess.

The matrix around the cells frequently stains in the same manner as the granules, though more faintly. Such pictures are unquestionably sometimes due to the action of reagents; they are of interest as indicating the soluble and diffusible nature of the material composing the granules. Ehrlich and Lazarus[1] cite Unna's descriptions of these stained zones about mast-cells as evidence for the secretory nature of the granules.

Usually it seems to be taken for granted that mast-cells are capable of ameboid movement, but it does not appear that such movement has actually been seen. The highly irregular outlines which they not rarely show, no doubt resemble those of moving amebæ. Their occasional presence between the epithelial cells of the skin, argues for their having ameboid movement. A case of myelogenic leukemia has recently been described, the peritoneal fluid of which was rich in mast-cells, which were supposed to have migrated into it.[2]

Evidences of phagocytosis are not often found. Unger also ascribed an important function to these cells in transporting droplets of fat in the active mammary gland.[3] Concerning their origin and manner of multiplication, little evidence is at hand. Mitoses seem not to have been observed. Bäumer who found mast-cells numerous in the lesions of an artificial urticaria, believed they originated from the connective tissue cells of the adventitia of the vessels. The connective tissue cells, not the mast-cells, showed mitoses. The abundance of mast-cells about the vessels when they are present at all, and their increase in hyperemic conditions, are well known.

Concerning their occurrence in normal and pathologic

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Pathology and Bacteriology, and approved for publication by the Executive Committee: Drs. A. Stengel, W. S. Hall and L. Hektoen.

tissues,[5] so much has been written that it will be necessary to adhere closely to the subject of their behavior in the infections. However, their wide distribution among animals and at all periods of life must be noted, as indicating that they have important functions in the normal organism. It is remarkable that they are numerous in the tissues of the rat and rare in those of the nearly related rabbit and guinea-pig. Coen found that they quickly appeared in the skin of the rabbit or guinea-pig in which they do not usually occur, after irritation with iodin.[6]

Mast-cells are uncommon in pus and in muco-purulent discharges. Although it does not appear that any special search has been made for them in acute infectious diseases, the histologies of the infections have been so carefully worked out that they could certainly not have been overlooked. Upon reading recent studies of acute infections of all sorts, one finds that while mast-cells are frequently present in and around the lesions, they have not been seen in such numbers or so arranged that any specific relation has been ascribed to them; as, for example exists for eosinophiles in acute trichinosis. The writer's experience would lead him to adopt a similar view. An exception to this opinion is found in an article on the changes in the tissues produced by experimental bubonic plague, where mast-cells were found in the diseased lymph-nodes in such numbers as to lead the author[7] to believe they perform an important rôle in plague.

In chronic infectious diseases, especially tuberculosis, mast-cells are usually present in the zone of reactive inflammation about the lesions, where they may be numerous. The lesions themselves do not contain them in large numbers, if at all. There is nothing to show that the infectious element causes this increase. The writer has more often found mast-cells very numerous in such material as scrapings from chronic endometritis, uterine myoma, or carcinoma of the breast or lip, than in the vicinity of tubercles or gummata. It should be noted that in myelogenic leukemia the blood contains an increased number of mast-cells, if leukemia be regarded as an infectious disease. Turk has claimed that the parasites described by Löwit[8] for leukemia are mast-cell granules.

In general it may be said that where mast-cells become increased, plasma-cells are likely to be present and in much larger numbers than the mast-cells. This parallelism is not close, however. The writer's impression is that plasma-cells appear to be more definitely connected with infectious processes than mast-cells. The formation of tumor-like masses, often seen with plasma-cells, has been described for mast-cells only in urticaria pigmentosa.[9] The writer has recently had an opportunity to secure a striking confirmation of Unna's observation in a case of urticaria pigmentosa.

It appears from the preceding that evidence is at present lacking to prove that mast-cells have any special relation to infections in general or to any particular infection. But it must be said that the subject has not yet received the study that it deserves. The facility with which these cells may be demonstrated, the large size of their granules, and the exhibition of characteristic reactions by the granules make them a promising field for research.

SOME INVESTIGATIONS UPON ANTIVENENE.*

JOSEPH McFARLAND, M.D.
PHILADELPHIA.

The investigations of the last decade upon immunity to the infectious diseases have led to the discovery of many important and interesting facts. Among the most instructive of these we may mention the successful immunization of animals to serpent's venom achieved by Wolfenden, Phisalix and Bertrand, and Calmette, and the discovery in the blood of the immunized animals of a specific protective substance, first demonstrated by Phisalix and Bertrand, and elaborately studied by Calmette and Fraser.

THE METHOD OF IMMUNIZATION

adopted by Calmette consisted in the administration to horses of progressively increasing doses of cobra venom, slightly modified by heat, until the animals attained a high degree of immunity and antivenene appeared in large quantity in the blood.

COMPOSITION OF VENOM.

It has been well known for many years that the venom of serpents is not a simple poison, but one composed of several distinct poisonous proteids of different physiologic action. In their great monograph upon the subject, Mitchell and Reichert concluded that every venom contained two important poisonous proteids, one of which they regarded as a peptone, the other as a globulin. The former was a nervous poison, whose chief physiologic action was upon the center of respiration, upon which it acted so destructively that nearly all cases of venom intoxication die from more or less rapid failure of the respiration. The globulin they found to be an irritating substance with a marked local action upon the tissues, which it devitalized and disorganized, causing extensive extravasations of blood, necrotic and gangrenous changes, and leading to death from the local injury done. Wolfenden agreed with Mitchell and Reichert except that he regarded their peptone as an albumose, and since the time of these investigations it has been generally accepted that the activity of venoms depends upon the presence of these two bodies, and that the difference in the symptomatology of snake bite depends upon the different proportions in which these active principles are present in the venoms. Thus, the venom of the cobra—*naja tripudians*—contains much of the nervous poison, and but little of the irritative poison, hence cobra bites are apt to cause comparatively little local damage, though they may prove fatal. On the other hand, the venom of the rattlesnake contains relatively less of the nervous poison, and a large quantity of the irritative poison, so that the bite of this snake is apt to be followed by extensive local damage, though usually not fatal.

Calmette found that when venoms were heated to 70-85° C., the irritative poison was precipitated, the nervous poison almost unchanged. The heated poison could be introduced into animals without pain, and

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Pathology and Bacteriology, and approved for publication by the Executive Committee: Drs. A. Stengel, W. S. Hall and L. Hektoen.

without tissue disorganization. It was the fatal element of the venom, and suggested itself for the purpose of immunization. All of his antivenene experiments were, therefore, performed with this nervous poison which he secured from cobra venom—the most active venom that could be obtained.

C. J. Martin has taken exception to Calmette's antivenene on the ground that it is an antidote for the nervous poison in the venom, but not an antidote for the irritative poison, and, therefore, is probably not useful or indicated in the bites of those serpents whose venom depends principally upon the latter. He found it inefficient in the treatment of the bites of Australian snakes, whose venoms all contain large quantities of the irritative poison. A literary controversy followed the publication of Martin's views, but it is uncertain whether Calmette succeeded in overthrowing all of his objections.

ITS ACTION.

We must, in consequence of these facts, view the antivenene as being antidotal chiefly against the nervous poison of the venom, the peptone of Mitchell and Reichert—the albumose of Wolfenden. A simple experiment suffices to demonstrate the perfect protection which the antivenene affords against the venom. According to Calmette's recommendation, an inoculation of a quantity of venom that will prove fatal in about twenty minutes is made into the marginal vein of a rabbit's ear, and this at once followed by the appropriate quantity of antivenene. Instead of dying at the expiration of the twenty minutes, the rabbit lives and shows no symptoms. If this curative effect is accomplished by 2 c.c. of the antivenene—the strength made by Calmette—it is said to contain 2000 units.

The protection I have found to be exactly as Calmette asserts and the antivenene is equally active against cobra, rattlesnake and other venoms, when such venoms are heated so as to remove the contained globulin. If the venoms are injected into the ear vein without being heated, the protection afforded is less certain, and if the viper and rattlesnake venoms are injected beneath the skin, still less certain. I did not find that the antivenene afforded complete protection against the local effects of crotalus venom, though it seemed to lessen them.

SOME IMMUNIZATION METHODS.

In some experiments which I was permitted to perform through the kindness of H. K. Mulford Co., I began the immunization of the animals according to the principles laid down by Calmette, beginning the treatment with cobra venom heated to 80 C. to precipitate the globulins. After a short time it occurred to me that if my serum was ever to be used for treatment, it would probably be in this country, where the irritative venoms of the rattlesnakes, moccasins and copperhead snakes are to be combated, and that a serum to have the desirable protective efficacy should protect not only against the nervous poison contained in the heated venom, but also against the irritative globulin as well. I therefore determined to abandon Calmette's method, give up the use of cobra venom, and confine my endeavors strictly to the immunization of the animals with the most irritative venom I could obtain, administered in its natural condition. I therefore began to work with unmodified crotalus venom.

Three horses were used for the experiments, two of them dying early in the treatment. I found that while they bore the initial injections of heated cobra venom without inconvenience, they responded by a violent local reaction to each injection of crotalus venom. The injections were made into the subcutaneous tissue of the neck and each was followed by a very considerable swelling of the tissues, succeeded in every case by an infection resulting in a good-sized abscess and slough. Sometimes enormous areas of skin and subcutaneous tissue became gangrenous and exfoliated, leaving lesions that required considerable time for cicatrization. One horse died from an exceptionally severe local lesion.

After pursuing this mode of inoculation until the death of the one horse and the condition of the others persuaded me that it could not be further continued, and proving that the injections were followed by no local or general immunity to the irritative poison, I decided to try the effects of the injection of the unmodified venom into the venous circulation. The appropriate dose of venom was much diluted with water and slowly introduced into one of the superficial veins, where it was at once further diluted by the blood. This mode of administration was not followed by any local lesion, and produced no symptoms of long duration. In nearly every case the injections were succeeded by a febrile reaction, and for a time—usually less than 12 hours—the horse seemed depressed and weak, and refused to eat. After the lapse of this period the animals seemed well, ate and drank normally, though it must be said that their condition was continually below par. It is quite probable that they might have remained in better shape if the administrations had been less frequent and each dose smaller. This fact, however, only became apparent after the experiments were at an end and the results obtained subjected to careful consideration. During the experiment the matter was left to the discretion of Dr. E. M. Ranck, the veterinary surgeon in charge of the animals. The venom seemed to increase the susceptibility to infection. This probably depended upon the alteration in the germicidal action of the blood, pointed out by Professor Welch and Dr. Ewing, in 1892, at the First Pan-American Medical Congress. Not only was this diminished action shown by the tendency to local inflammations and necroses, but also by a tendency to general infection, for while I lost the first horse in consequence of destructive superficial lesions, the second animal died of pneumonia.

As the doses of venom were increased, the immediate physiologic effects became more and more marked. The venom was slowly injected into the vein, but about the time the total quantity entered the circulation the horse would become unconscious and fall suddenly to the ground. After a few minutes in this condition, with marked cardiac and respiratory disturbance, consciousness gradually returned. The functions re-established themselves and the animal would pull itself together and get up again. After witnessing this phenomenon several times, the horses were supported by "slings" before the injections were given in order that no injury might result from the fall. No serious damage seemed to occur in consequence of the momentary extreme depression, and after a time we came to look upon it without fear.

The early injections of modified cobra venom need not be considered. The treatment of the animals is, therefore, to be divided into these three periods: 1. In which crotalus venom, modified by heat, as suggested by Calmette, was injected subcutaneously. 2. In which unmodified crotalus venom was injected into the subcutaneous tissues. 3. In which unmodified crotalus venom was injected into a vein. The following table (Horse 592) shows the complete treatment of the horse that survived longest and finally yielded to antivenene. The

second table (Horse 774) shows a horse begun at once with intravenous injections. It died of pneumonia. The third horse was begun with subcutaneous injections of unmodified crotalus venom, but died from the effects of the superficial lesions caused by the fourth or fifth injection, so that it is not worth while to introduce his brief treatment.

SCHEME OF THE IMMUNIZATION OF HORSE 592.

1. Heated crotalus venom used for immunization, as suggested by Calmette:

May 30, 1899, 0.01 gram venom; slight local swelling.
June 7, 1899, 0.01 gram venom; slight local swelling.
June 16, 1899, 0.01 gram venom; slight local swelling.
June 21, 1899, 0.1 gram venom.
June 26, 1899, 0.15 gram venom.
July 1, 1899, 0.15 gram venom; slight local swelling.
July 10, 1899, 0.15 gram venom.
July 15, 1899, 0.15 gram venom.
July 19, 1899, 0.20 gram venom.
July 26, 1899, 0.30 gram venom.
Aug. 8, 1899, 0.50 gram venom.
Aug. 15, 1899, 1.00 gram venom.
Aug. 30, 1899, 1.00 gram venom.
Sept. 11, 1899, 1.50 gram venom.
Sept. 19, 1899, 2.00 gram venom.
Sept. 27, 1899, 2.50 gram venom.
Oct. 7, 1899, 3.50 gram venom.

2. Unheated crotalus venom given subcutaneously.

Oct. 17, 1899, 0.50 gram venom.
Nov. 4, 1899, 1.00 gram venom; became ill and had a slough; first test failed.
Dec. 5, 1899, 0.50 gram venom; ill.
Jan. 12, 1900, 0.25 gram venom; ill.

3. Unheated crotalus venom given intravenously.

Feb. 24, 1900, 0.10 gram venom.
March 6, 1900, bled A; tests showed no positive protective power.
March 14, 1900, 0.10 gram venom; ill after injection.
March 27, 1900, 0.25 gram venom; ill after injection.
April 10, 1900, 0.30 gram venom; ill after injection.
Bled B; showed positive protection against crotalus and cobra venom.
April 18, 1900, 0.50 gram venom; ill after injection and unconscious for a short time.
May 9, 1900, 0.75 gram venom; ill after injection and unconscious for a short time.
May 31, 1900, 0.75 gram venom; ill after injection and unconscious for a short time.
July 10, bled C; lessened protective power.
July 10, 1900, 0.50 gram venom; ill after injection; fell unconscious.
July 30, 1900, bled D; lessened protective power.
Sept. 12, 1900, 0.27 gram venom; ill; fell unconscious.
Oct. 16, 1900, 0.50 gram venom; fell unconscious. Some of the venom accidentally caused a periphlebitis of the jugular region, with a large slough from which the horse died.

SCHEME OF IMMUNIZATION OF HORSE 774.

Feb. 24, 1900, 0.005 gram crotalus venom intravenously; very ill.
March 14, 1900, 0.005 gram crotalus venom intravenously.
March 27, 1900, 0.01 gram crotalus venom intravenously; very ill.
April 5, 1900, 0.0133 gram crotalus venom intravenously; very ill.
April 18, 1900, 0.02 gram crotalus venom intravenously.
May 9, 1900, 0.04 gram crotalus venom intravenously.
May 31, 1900, 0.10 gram crotalus venom intravenously.
June 20, 1900, 0.20 gram crotalus venom intravenously.
July 12, 1900, 0.33 gram crotalus venom intravenously; ill.
Aug. 1, 1900, 0.25 gram crotalus venom intravenously; ill; recovered from the injection in about two hours.
Aug. 17, 1900; 0.33 gram crotalus venom intravenously; ill; would have fallen but was supported by slings; recovered from injection in about two hours.
Aug. 20, 1900; developed pneumonia and died a few hours after the nature of the disease was determined.

Much interest attaches to the fate of horse 592, and the circumstances of its death are very instructive. After attaining a high degree of immunity, and tolerating the venom injections from May 30, 1899, to Oct. 31, 1900, and having received many intravenous injections and having recovered perfectly from all of the early superficial lesions, the horse gradually began to decline in condition so that it became necessary to diminish the doses of venom very considerably. The reduction in the dosage was followed by a positive gain in vital condition, and I was in hope that health was again regained when the accident occurred that provoked death. In giving the intravenous injection, Oct. 16, 1900, the needle slipped and permitted the escape of some of the venom into the perivascular and subcutaneous tissue. How much of the venom entered these tissues, and how much entered the vein is not known, but the result of the accident was the immediate occurrence of a large subcutaneous edema which by pressing upon the trachea threatened to cause death from suffocation. Tracheotomy was performed, but the damage done was too great to be borne and the animal died. Thus I think it is proven that from this whole course of treatment, no immunity to the local irritation of the venom was developed, but that the horse, even though able to endure the venom introduced into its circulation, was unable to endure its local action.

The blood of the animals was examined from time to time as the routine work permitted. Horse 774 never yielded any useful serum. The other animal, 592, developed marked antitoxicity, with the presence of a useful quantity of antivenene, but as is usual in antitoxic horses, the antivenene gradually diminished.

The method of testing the antivenene was that already outlined, as having been invented by Calmette. The determination of the dose of unmodified venom that would kill a rabbit was difficult.

SUMMARY OF THE TESTS MADE TO DETERMINE THE FATAL DOSE.

These tests are not put down in chronological order, but according to size in order that the result of diminution may be apparent. Absolute accuracy was not attained, but it was thought that the doses selected were reasonably accurate. The solutions used were 1 per cent. aqueous solutions of the dried venom, protected from decomposition by the addition of a small amount of carbolic acid. Adult rabbits (2 kg.) only were used for the experiments.

CROTALUS VENOM.

1.00 c.c.	standard	venom	sol.	inject.	into	ear-vein	Rabbit;	died.
1.00	"	"	"	"	"	"	"	"	"
1.00	"	"	"	"	"	"	"	"	"
0.75	"	"	"	"	"	"	"	"	"
0.75	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	lived.
0.50	"	"	"	"	"	"	"	"	"
0.50	"	"	"	"	"	"	"	"	died.
0.25	"	"	"	"	"	"	"	"	"
0.25	"	"	"	"	"	"	"	"	lived.

These tests show the difficulty met with in endeavoring to locate the fatal dose. My conclusion was that it was only safe to experiment with doses large enough to eliminate doubt as to the consequence of venom injection and after the early tests in which 0.5 c.c. was used as a test dose.

COBRA VENOM.

1.00 c.c. 1 per cent. aqueous cobra venom sol.; died in 2 min.
0.20 " " " " " " 15 "
0.20 " " " " " " 1 "
0.10 " " " " " " 2 "
0.10 " " " " " " ? "

The agkistrodon contortius (copperhead snake) yielded a feebler venom than the crotalus.

TESTS.

1 c.c. 1 per cent. aqueous solution dried venom; rabbit died.
1 c.c. 1 per cent. aqueous solution dried venom; rabbit lived.

I found that the preservation of venom in the dry state is almost permanent, as some crotalus venom, which I secured through the kindness of Mr. Thompson, keeper of reptiles at the Zoological Gardens of Philadelphia, after having been dried for more than ten years, was as strong as that freshly obtained.

TEST.

0.50 c.c. 1 per cent aqueous solution, injected into the ear-vein caused the death of the rabbit in 6 minutes.

Solutions of the dried venom in 1 per cent. carbolic acid keep almost indefinitely, especially if kept cold. I made a solution of this kind on February 21, 1900, testing it March 12, 1900, April 18, April 23 and October 3, 1900, without finding that it had changed appreciably. On the other hand, I found that when aqueous solutions were not protected by the addition of the antiseptic, they lost virtue, so that in 48 hours they were worthless. This difference, of course, depends upon the destruction of the venom by saprophytic bacteria.

I have no doubt but that it would have been much easier to accurately estimate the minimum fatal dose of any venom modified by heat. It was my desire, however, to protect against the other principle of the venom—the one precipitated by heat—therefore, I desired to work with unmodified poison. It is true that by injecting the venom into the vein I inhibited the action of this principle by excessive dilution, so that after all, all the protection that my antivenene afforded was probably against the nervous poison. However, concerning the blood of horse 592, the following tables will show what tests I made, and with what success.

The venom was always mixed with the serum before injection into the ear vein—this procedure differing from the method of Calmettte.

HORSE 592.

The serum was examined at five different periods during immunization, i. e., trial, A, B ,C and D bleedings.

In making the tests the animals chosen were adult rabbits of approximately equal size (2 kg.). Each received a known fatal dose of venom, which, except in the instances stated, was mixed with the serum tested, and injected into an ear-vein. As the serum sent me by M. Calmette was protective in doses of 2 c.c., I used that dose as a standard for comparison.

1. Period when no protective power was demonstrable; trial bleeding.

TESTS.

0.5 c.c. standardized crotalus venom + 4 c.c. serum; rabbit died.

CONTROL TESTS.

0.50 c.c. standardized solution; rabbit died.
0.50 c.c. standardized solution; rabbit died.
0.25 c.c. standardized solution; rabbit died.

2. Period of uncertain protection; bleeding A.

TESTS.

1.0 c.c. standardized solution of crotalus venom + 2 c.c. serum A; rabbit died.
1.0 c.c. standardized solution of crotalus venom + 2 c.c. serum A; rabbit lived.
0.5 c.c. standardized solution of crotalus venom + 2 c.c. serum A; rabbit died.
0.5 c.c. standardized solution of crotalus venom + 2 c.c. serum A; rabbit lived.

CONTROL TESTS.

0.5 c.c. standard solution; rabbit died.
0.5 c.c. standard solution; rabbit died.

3. Period of complete protection against crotalus venom.

TESTS.

0.75 c.c. standardized crotalus venom + 1 c.c. bleeding B; rabbit lived.
0.75 c.c. standardized crotalus venom + 1 c.c. bleeding B; rabbit lived.
1.00 c.c. standardized crotalus venom + 2 c.c. bleeding B; rabbit lived.
2.00 c.c standardized crotalus venom + 2 c.c. bleeding B; rabbit lived.

CONTROL TESTS.

0.75 c.c. standardized crotalus venom; rabbit died.
0.75 c.c. standardized crotalus venom; rabbit died.
1.00 c.c. standardized crotalus venom; rabbit died.
2.00 c.c. standardized crotalus venom; rabbit died.
2.00 c.c. standardized crotalus venom; rabbit died.

Partial protection against cobra venom.

TESTS.

0.1 c.c. standardized cobra venom + 2 c.c. Calmette's serum; rabbit lived.
0.1 c.c. standardized cobra venom + 2 c.c. serum B; rabbit lived.
0.1 c.c. standardized cobra venom + 2 c.c. serum B; rabbit died later.

CONTROL TESTS.

0.1 c.c. standardized cobra venom; rabbit died.
0.1 c.c. standardized cobra venom; rabbit died.

4. Period of decline of protective value.

TESTS.

0.1 c.c. standardized cobra venom + 2 c.c. serum C; rabbit died.
0.1 c.c. standardized cobra venom + 2 c.c. serum D; rabbit died.

CONTROL TEST.

0.1 c.c. standardized cobra venom; rabbit died.

HORSE 774.

As this animal stood the immunization very badly and was ill or supppurating most of the time before its death, only once was blood taken for examination; bleeding A.

TESTS.

1.0 c.c. standardized solution of crotalus venom + 2 c.c. serum A; rabbit died.
1.0 c.c. standardized solution of crotalus venom + 2 c.c. serum A; rabbit lived.
1.0 c.c. standardized solution of crotalus venom + 2 c.c. serum A; rabbit lived.
1.0 c.c. standardized solution of crotalus venom + 2 c.c. serum A; rabbit died.

CONTROL TESTS.

1.0 c.c. standardized solution of crotalus venom; rabbit died.
1.0 c.c. standardized solution of crotalus venom; rabbit died.
0.5 c.c. standardized solution of crotalus venom; rabbit died.
0.5 c.c. standardized solution of crotalus venom; rabbit died.
0.5 c.c. standardized solution of crotalus venom; rabbit died.
0.5 c.c. standardized solution of crotalus venom; rabbit died.

From these tests it may be inferred that the serum was possessed of a feeble protective power. The tests are too few to be conclusive, but as the serum was lacking in the desired protective power, and as the horse died subsequently, it was not deemed worth while to pursue the matter further.

In some cases not included in the tables, the injected mixture failed to enter the vein, or only part of it entered. In these cases the invariable result was the formation of a large superficial necrosis, and sometimes the loss of most of the ear.

CONCLUSIONS.

From these experiments I think it is safe to say that:

1. It is not difficult to produce immunity to the nervous poison contained in serpent's venom, as shown by Wolfenden, Phisalix, Bertrand and Calmette.

2. This immunity when carried to a high degree is associated with a marked antitoxic power of the blood.

3. It is very difficult if not impossible to produce immunity to the irritative poison of the venom.

4. Antivenene does not protect very powerfully against the irritative poison.

5. Antivenene protects against the nervous poisons of various venoms.

6. Immunity to the unmodified venom is better secured by intravenous than by subcutaneous injection.

7. Calmette's method of immunization with the modified venom is greatly to be preferred to the method of immunization to the unmodified venom as tried in these experiments, because of the modicum of danger and suffering to the horses used.

8. Calmette's antivenene is more useful for the treatment of the bites of cobras and colubrine serpents than for those of vipers, etc.

9. As the antivenene protects against the chief death-dealing element in the venoms, it is of great use in the treatment of all serious bites, and should be used whenever possible.

10. The neutralization of the nervous poison of the venom by antivenene will enable the individual to devote all his vitality toward overcoming the local injury done by the irritative globulin in the venom.

11. All individuals—certainly not all horses—are not equal in their resisting power against venom. Two of my three horses succumbed quickly to the venom injections.

12. The antivenene producing power varies in different horses.

13. The quantity of antivenene in the blood varies from time to time, according to circumstances.

A CASE OF LOCALIZED AMNESIA.*

EDWARD E. MAYER, A.M., M.D.
PITTSBURG, PA.

The following case illustrates one of those interesting phases of abnormal psychologic experience, which have been occasionally noted in actual life, and which have as often been made the subject of novels. When used in literature they are looked upon as the invention of an imaginative mind, yet observations of scientific men have shown even more novel and seemingly impossible instances than are portrayed in books. The cases of Macnish, Sidis, Azam, Dufay and others have been made the subject of much comment, and the works of Azam, Ribot, Binet, Sidis, Richet, Tuke, Maudsley and writers of this class have helped to lift the clouds that surround our conceptions of consciousness and personality. The following case of amnesia presents such very peculiar features that it has been thought of sufficient interest to warrant its presentation.

Charles W. was born in Eastern Pennsylvania in 1860. His father and mother became separated, though keeping up a communication with each other. In 1884, the son, hearing of his father's death and knowing that the latter had some property in the West, where he had lived, set out to investigate. Traveling west from Chicago, he had gone but a short distance when the train was wrecked. That was seventeen years ago. He remembers at the present time that there was a crash, that he felt himself hurled through space, and then—nothing. In February of this year he became unconscious and after twenty-four hours, when he awoke, the seventeen years between the accident and the present had been completely obliterated and he had gone back to the time of the accident. He thought that he was 24 years of age, as he had been at that time, and he recognized neither his wife nor his own children; in fact, he had no knowledge of ever having been married and had also forgotten his business and his friends. He was an entire stranger in the city where he had lived for a long time, and the trolley cars upon which he had ridden for years, and the electric bells which he had used repeatedly, were as strange to him as upon the first time that he saw them.

WHAT HAPPENED IN THE SEVENTEEN YEARS.

The first five years after the accident are lost. Mr. W. has no remembrance of anything that happened, neither is there any one known who can tell of his life during that time. Twelve years ago he first came to Pittsburg; there he met his present wife, and two years later they were married. She has supplied the information as to the details of his life up to the present time. We present only that which has a bearing upon our subject. At no time during these twelve years did he give any information concerning his previous life. Insistent questioning on the part of his wife always failed to reveal anything. He had, however, always remembered his name; that point should be especially noted. Shortly before his oldest child was born, nine years ago, he wandered away one Sunday afternoon and did not return until Monday evening. This was exceptional with him, for he never went out, other than to work, unless his wife accompanied him. He was a total abstainer, therefore alcohol could not have been responsible for this action. His only answer as to where he had gone, was that he had been out riding.

About a year later, eight years ago, while painting a house with his brother-in-law, he suddenly stopped work and went away without saying anything by way of explanation. Two days later a postal card was received from him, written at his mother's house, so he wrote, and telling his wife that he would be home in a day or so. This is the first knowledge his wife had that his mother was living, but ever afterward he remembered her. The memory of his mother seemed to have come to him suddenly, and, acting impulsively, he had instantly gone to visit her.

During these years he worked in succession at farming, running a sawmill and painting. He was at times afraid to come home, his wife states, and seemed constantly downhearted and worried. So moody did he become that she was afraid to leave him alone with the children.

He was always affectionate, was a kind husband and a good father. He suffered much from sick headaches, the pain of which would make him almost frantic. He would often moan in his sleep, but was never somnambulistic. While conversing he would often stop in the midst of a sentence and commence anew without seeming to realize it. He had an attack of painter's colic several years ago, but the exact time is not known. Some time ago he began to have violent pains over the right hepatic region, and this region began to swell up, "long strings of corruption," as his wife styled it, being passed through the mouth. The condition was relieved somewhat by free action of the bowels and kidneys, but it recurred monthly for a time; later the intervals became longer and the suffering less in intensity with each attack. The pain, however, was present between the attacks, and to such an extent that no one could sleep with him on account of his restless tossing from the pain.

Dr. S. G. Small, his physician at that time, diagnosed the condition as one of hepatic abscess. The slightest

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

touch over the liver region caused intense pain. The last attack was on February 23, 1901, and he was walking the floor of the dining-room, suffering intensely, when a daughter who was in the room accidentally overturned the lamp. Mr. W. tried to catch it as it fell, but as he reached for it murmured, "Oh, my head," and fell to the floor unconscious. He was put to bed and Dr. Small summoned, but all attempts to revive him remained futile. About 4 a. m. he awoke for an instant, but again went to sleep. He awoke some time in the morning, asking, "Am I much hurt?" His wife wonderingly replied in the negative, and he then inquired as to what hospital he was in and asked whether she was the nurse. Upon being told by her that she was his wife he resented it by saying that he was not in the mood for joking.

After sending for the doctor, in obedience to his request, she asked him whether he wanted to see his children. "I'm not married," he replied. "It's a nice thing for a man 24 years of age to wake up and be told that he is the father of four children." "But you are not a young man," persisted his wife. Finally a mirror, pictures taken of him at various intervals, his marriage certificate, and the various exclamations of the four children who were brought in, convinced him of the truth of her statements. He did not recognize the doctor, to whom he insisted that he felt entirely well. No further evidence of hepatic abscess was present and he had not the slightest feeling of pain, being able to stand quite severe blows where formerly the merest tap was excruciatingly painful. The next day he came under the care of the writer.

PRESENT CONDITION.

I found a man of spare build, 5 feet 9 inches high, weight 132 pounds, spanning 5 feet 11 inches from the tips of one hand to the other. His head was 22 inches in circumference and 12.5 inches from glabella to inion. The long bones were all well formed, but his chest was slightly carinated. His musculature was under-developed, the dynanometer showing 42 on right side and 40 on the left. Both deep and skin reflexes were about normal. His pupils were wider than normal and reacted slowly to light. All ocular muscles functionated normally. His head and face are asymmetric, ears badly set and protruding, but not very badly formed. His lips are thin and compressed, his teeth uneven and irregular, and the palatal arch is very high. Upon the right side the labial folds are much slighter than upon the left, and he shows traces of a former right facial palsy; however, no history of it can be obtained. He gives a totally negative family history and all his children are healthy except Ruth, who is 7½ years old and did not speak until she was 6 years of age. She was born with "the cord around her neck," the mother says. She is choreic and when sent to school last fall she was sent home by the teacher with a note saying that as she constantly slept in school, she had better be kept at home. She is a middle-grade imbecile.

This patient presents nothing pathologic upon examination of his various organs. Sexually he is normal, his wife having again become pregnant recently. His childhood, which he now remembers, reveals nothing abnormal. Attention, judgment, perception are all good. He has a high moral sense, never smoked or drank, has been a steady church-goer, and is now considerably worried for fear of having done something wrong in the five years after the accident, as his actions during that time are totally unknown to every one whom he now knows. His memory for recent events and for those up to 1884 are perfect. Close questioning by myself and also by various members of the Pittsburg Academy of Medicine, before whom he was presented, failed to detect any error or lapse in his story.

At the present time he passes his former friends in the street without recognizing them, and is much embarrassed when accosted by any one. He must be closely directed else he will miss his way on the street. When going to consult the doctor he stood outside until noticed, not finding any knocker and never, so far as he knows, having seen an electric bell before. The same is true with all the modern improvements he sees.

On account of his illness of the last two years he had been compelled to quit work and his wife had opened a small grocery store. He had spent his time, as far as able, in delivering goods in the neighborhood or in taking orders for the store. He is now ashamed of the condition that he finds his "new" family in. In going over the books, something he had never done before, he rebuked his wife for the careless way in which they were kept. He did not remember the customers that he had daily called on for orders.

He has spent much time picking up the details of his old life, relearning it from his wife's lips. His memory seems to be very retentive, but his wife says that formerly he was very forgetful. Being anxious to better things, his friends secured for him a position at his old trade. He found that he did not know anything about it, but his employers were kind to him and he began to relearn it, but only able to earn the wages of an apprentice, while formerly he had been able to command one of the highest salaries in the city at his trade. He began to have heavy depressing dreams. It seemed that their central idea was one of being declared insane and being sent to an asylum—the comments of his friends, the strangeness of his life and the unfortunate newspaper notoriety given him worrying him very much. On March 8 he left home at 8 a. m. for work. He did not return until 9 p. m., staggering like a drunken man, weak and exhausted, and declaring that he found himself at 5 p. m. in Greensburg, about 30 miles away from his home, and took the next train home. He had no recollection of going there nor can he give any reason. Information reached us later of his having stopped at a wholesale house in the morning and of his ordering some goods for his wife's store. The salesman reported that he seemed dazed and confused at that time. The next day, his wife not knowing this, she gave him $25 with which to buy groceries. He left home and did not return. No trace of or word from him has since reached us, and he seems to have entirely disappeared from the face of the earth.

This is then Mr. W.'s history. We shall make a few remarks concerning his condition, not, however, going into detail, as what we might say would be only a rehash of the writings of Ribot, Binet, Sidis and others.

EXPLANATION OF CONDITION.

What constitutes memory? It is plainly the consciousness or recognition of events and impressions. These must be retained or reproduced, but unless recognized by our conscious ego would not be remembered, psychologically speaking. Impression and reproduction are the two essential elements of memory, but, unless we can localize, we are not conscious of the first two. Studies in amnesia or loss of memory have shown that it is first confined to recent events, and embraces, in turn as it progresses, ideas, sentiments, affections and actions.

In the present case the amnesia may be called localized after the classification of Boris Sidis, because it embraces a definite period of time. We have with him similar alterations of personality to what we see in somnambulism and petit mal, where we find the presence of certain automatic acts, but without the other factors of conscious personality. A difference, however, lies in the fact that in one case memory localizes the acts, in the other it does not; but in both cases we have the impressions of acts or ideas and their reproduction. Mr. W.'s loss of memory was not complete, and it is rare to find a complete amnesia. His remembrance of his name, his retention of the automatic acts of speech, walking, etc., are examples.

We see also in the sudden remembrance, eight years ago, of his mother's name and address, an interesting example of an impression present in the subconscious mind, welling up, becoming recognized by his conscious ego and becoming a conscious memory. It is probable that in these seventeen years many other old memories were revivified, but were not localized for any period of time, or were not strong enough to be actively remembered.

The patient's condition during these seventeen years was not, from what we can gather, a normal one. His moodiness, his fits of abstraction amounting at times to a condition of distraction, reveal this. He would often sit when talking to someone, staring intently into space as if he wanted to look through them, as they expressed it. This was particularly noticeable in recent years, after his attacks. The picture, which I will pass around, taken after one of these attacks, shows vividly his abstracted, staring look and an ocular paralysis, which is not present now.

Were these periods of changed personality, of transient duration, so slight as not to be recognized? Were they simply conditions of alternated personality, unnoticed by his ego, in which subconscious memories were active? No one can say. We know that the conscious and the subconscious are ignorant of each other. It seems as if the lower consciousness is able to arise to the surface and take charge of things, the individual showing no signs of having once known the other—the conscious ego. Professor James' case of Rev. Ansel Browne and Osgood Mason's case of Alma Z. shows this.

It may be that Mr. W.'s case is an example of dual personality, often seen as a manifestation of epilepsy. The fragmentary account, as given to us, of his previous life, seems to indicate the presence of psychic automatism at times. Those temporary attacks of abstraction and his frequent stopping in the midst of a sentence are very much like petit mal. Consider in this light the latter period of his history, when observed by us. His wandering to Greensburg, awaking there unconscious of how he had come, his mind a perfect blank concerning the five or six hours which had preceded; this is similar to what we observe in procursive epilepsy. His second wandering, no knowledge of his whereabouts for the last eight weeks having been obtained, might be the result of another alteration in personality similar to what had happened before in his history.

Consciousness is not a simple matter; in fact, we do not have a single consciousness, but states of consciousness, just as we do not have a will but volitions. It must not be supposed that we can sharply divide organic from psychic memory. All stages of transition exist, from the purely subconscious to the conscious. With Mr. W. we seem to have a sudden transition, due to cerebral shock, with just as sudden a change to his primitive memory, after a lapse of seventeen years. This was almost a complete change from conscious to subconscious memory. But it is extremely probable that he presented transient changes in the intervals, so slight in intensity, so short in duration, that he was not cognizant of them, except, as in dreams, for the time being.

HYPOTHESES.

Two hypotheses have been given to show the cause of such amnesias: 1, "the registration of anterior states being effaced;" 2, "the conservation of anterior states persisting, their power of revivification by association with the present being destroyed." Mr. W.'s case seems to show the truth of the latter hypothesis. If the registration of anterior states were effaced, would they so suddenly recur after a lapse of seventeen years? Is it not more probable that they were suddenly revivified by being associated in some way with the present and the memory of the seventeen years at the same time becoming disassociated? We see that the semi-organic memories, i. e., speaking, walking, etc., remained intact, they were permanent, automatic, while personal impressions were entirely inhibited. In his case they were not destroyed but were simply suspended, as they returned in full intensity after an absence from consciousness of seventeen years. This is what is called by Sidis a dissociation of moments of consciousness. It is according to his views a dissociation, not of individual cells where impressions are supposed to be stored, but of the cellular groups or memory as we all know is not a simple state but a very complex one. We have in addition to this dissociation, a disaggregation of the cells, a breaking up of cellular complexes.

Amnesia has also been explained physiologically in accordance with the neuron theory. The cells which are joined by their terminal processes unite to form groups, then systems, communities, clusters and constellations. The more complex these associations are the more unstable it is. When amnesia is complete we have a retraction of terminals and of fibers down to the final ones in the nerve cell itself. This hypothesis, founded on the retraction theory of the neuron, not yet proven itself, must wait before it can be accepted. In fact, we have no adequate explanation of these processes.

No one has proven that cells receive and store impressions. We accept the hypothesis of idea-association centers on the path between the sensorial gateways and the motor centers, without it having been proven, though from the destruction of certain parts of the brain causing aphasia and the like, we are almost warranted in doing so. Many of us believe in the vibratory theory concerning the receiving of impressions, but the fact remains that the exact nature of these processes remain unknown and perhaps unknowable. Wernicke's recent hypothesis and his sejunctive state, which figures in it so prominently, is also ingenious but not conclusive.

Attempts were made to study Mr. W.'s psychic processes during the time that he was under observation, but with no results. His dreams never revealed anything of his past, forgotten life, and his entire waking period was dominated by the fear that his strange experience would lead to his incarceration in an insane asylum. Attempts to suggest to him proved unavailing, yet his mental equipoise was increasing, calm was succeeding anxiety, and his weight had increased eight pounds in six weeks. Then he suddenly vanished from all the life he had known.[1]

1. Later.—September 2, 1901, Mr. W. came back to Pittsburg.

DISCUSSION.

DR. T. D. CROTHERS, Hartford, Conn.—This is one of the very rare and unusual cases we sometimes hear of, and it has been studied with a great deal of care. These patients are examples of a subconscious state, and offer a promising basis for new fields of study. They furnish the outline of a new phase of psychologic study which will receive more attention in the future than it has in the past. Dr. Mayer's case is a phenomenal one in many particulars.

DR. J. H. MCBRIDE, Los Angeles, Cal.—Pennsylvania seems to be a paradise for cases of this order. In the Mary Reynolds case reported by Weir Mitchell there was a number of times in a long life a complete amnesia of her previous personal history, with the development of a new and different consciousness, during which a restless and aggressive personality took the place of the former quiet and retiring one. The case of the clergyman Ansel Bourne, of Rhode Island, is interesting in this connection. He disappeared suddenly, and some months later was found running a little shop in a village in Pennsylvania, to which state he went when his old consciousness was so suddenly swept away. While in Pennsylvania he seems to have had no recollection of his home, family or previous life, but very suddenly one day his old consciousness returned to him and he was greatly alarmed to find himself in strange surroundings. Professor James hypnotized him and reproduced the amnesic state, and while hypnotized he failed to recognize his wife and friends and could not recall his name or residence.

DR. C. EUGENE RIGGS, St. Paul—About five years ago at the Salpêtrière, I had my attention called to a case of dual consciousness which had existed practically during the life of the patient. At certain times she was an ignorant and uncultured woman; at others she was educated and refined. These two striking contrasts in her mental condition were very interesting. Some years ago one of my medical friends in this city sent me a case of nocturnal epilepsy. The patient was a commercial traveler who spent most of his time on the road. After one of these epileptic attacks he would go from town to town, take orders from his customers, write letters to his firm, and yet be absolutely unconscious afterwards of what he had done, nor were those with whom he came in contact during one of these spells aware that he was not in his normal condition.

DR. HAROLD N. MOYER, Chicago—We have recently had in Chicago a case strikingly similar to the one described by Dr. Mayer. Unfortunately, we were not able to get the early history of the patient. About three or four years ago she had a sickness, the nature of which I was not able to learn, and upon her recovery there was complete loss of memory for a period of about four years preceding her illness. When I saw her she had no recollection of the last eight years of her life. It was found impossible to re-educate her, as she was utterly incapable of registering impressions for a period longer than a few seconds. Her mental condition corresponded perfectly to what you would expect from a person who had lost the power of registering mental impressions. Her reasoning powers were not affected only in so far as she was unable to register impressions and retain them.

DR. W. A. JONES, Minneapolis—Dr. Mayer's paper has recalled two or three cases that have come under my observation. The first case occurred in London, and it was looked upon as one of those cases of mysterious disappearance. The man disappeared from home, assumed another name, engaged in another occupation, and after a number of months returned. He was unable to recall anything that had occurred during his absence from home. Dr. Ferrier regarded it as a case of epilepsy of a peculiar type. A man in Omaha, with a neurotic family history, suddenly left home, and when he regained his former mental condition, which was several months afterwards, he found himself at work in a lumber-yard. His hands showed the effects of hard labor. Subsequently, he became an Eddyite lecturer, and he continued at this work until he had trouble with his board of managers. He has since renounced Eddyism and gone back to his original business. A young man in Minnesota suddenly left home. He found himself on a steamer in mid-ocean. Subsequently, he borrowed a large sum of money, which he spent in London, and returned home. He was then sent to a hospital for the insane, where he is still an inmate.

I recall a man coming from Iowa who was supposed to have epilepsy. He suffered from attacks of temporary unconsciousness, which he described as coming on with a peculiar sensation; his head apparently was lifted from the shoulders, and he could watch it as it gradually disappeared. Following this sensation, he had periods of partial consciousness lasting for hours or days. Suddenly his head would appear as a speck in the distance and gradually approach and settle on his shoulders, and then he returned to his normal state. We subsequently discovered that this man was under indictment in Iowa for having made away with a large sum of money, and that he had left town to escape arrest. In some of these cases it is pretty difficult to decide whether the person is suffering from an improperly received and improperly discharged impression, or whether he is an example of a peculiar type of degenerate, and is clever enough to assume these abnormal conditions. Some of these cases are no doubt genuine, while others are open to question.

DR. F. SAVARY PEARCE, Philadelphia—Last year, while investigating the subject of deaf-mutism, I saw a report that a man in Pittsburg who had been deaf for a long time had had his hearing suddenly restored. In order to verify the report, I sent an inquiry to the editor of the *Pennsylvania Medical Journal* (See August, 1900, issue), and was informed that a man, 69 years of age, who since twelve years of age had been a deaf-mute following ear disease; had fallen from a ladder and sustained a slight shock. Shortly after this he began to speak well and intelligently and his hearing was restored in one ear. The question arises whether he had been malingering all these years. Since then I have seen the same case reported in the January, 1901, Number of the *American Annals of the Deaf* by a layman. The man is no longer a deaf-mute. This whole subject again brings up the theory of the possible motile activity of the neurons. Usually an injury forms part of the history of these singular cases, and there is no doubt that injuries frequently cause great disturbance in the nervous system, whether we understand the mechanism of the changes that occur or not. The so-called neuron theory will satisfactorily explain away normal association and co-ordination of nerve force; and certainly offers a beautiful explanation of the phenomena cited to-day, i. e., some forms of amnesiæ, certain double conscious states, and restored hearing and speech as in the case I mention.

DR. EDWARD E. MAYER, in reply—Many of the cases cited by the gentlemen who took part in the discussion seemed to be

---

His wife had gone to the Union Station to seek work as a car-cleaner, having had difficulty in supporting herself after their savings had gone. There she met a man who had just stepped off a train. He held out a piece of paper and asked her if she could direct him to the address. It was one of my letterheads, which he had found in his pocket. She then recognized him and took him home. He had left home on the 9th of April. Upon the 11th, he found himself in a hotel in Wheeling, W. Va., was asked to register and, confused, wrote down a name, which he retained till his return. His own name and all recollection of the past were forgotten. He wandered around, found work as a painter, and at last determined to seek me out and try to find out who he was. His employers dissuaded him from leaving for some weeks, he claims, after finding my address in his pocket. He is depressed and moody, reticent and suspicious, does not recognize me and refuses to allow me to examine or interrogate him. Formerly he was friendly and loquacious. Since he has returned home (till November 4) he has had three attacks, in which he feels dazed, like he was walking on air, voices appear muffled to him, and he says that he does not feel like the same man at those times. This condition lasts about two days, but does not prevent him from working (painting). He has a constant headache and looks badly. Is much emaciated, restless, and very downcast. His wife is worried at his statements, but does not notice anything wrong. His memory is as it was before he left, but he does not remember what happened from April 9 to 11. This looks very much like a phase of epilepsy, but I have not seen any of these attacks myself, and only have his statements of them. He refuses to see me or any other physician and further questioning by me at his home elicited nothing additional to what is noted above.

true examples of ambulatory epilepsy or somnambulism, and not, properly speaking, cases of localized amnesia. In my case the length of the period of amnesia, namely, seventeen years, is remarkable, as well as the sudden onset from a severe psychic shock with the sudden return of his original conscious memory. This seventeen years' lapse was in my mind not epileptic. Suggestion was tried upon him in all different ways, with no result in bringing out any details. In answer to Dr. Crothers, I would say that all memory of his previous occupations had been entirely lost.

THE TREATMENT OF FRACTURES OF THE FEMUR WITH THE AMBULATORY PNEUMATIC SPLINT.*

WALTER B. METCALF, M.D.
CHICAGO.

The treatment of fractures of the femur has from time immemorial been an ungovernable condition, never fully under the control of the surgeon. The condition has been a source of anxiety to the surgeon and not an infrequent source of deformity to the patient. The injury has invariably resulted in shortening, which varied in amount from three-fourths of an inch to three and one-half inches, and in rare cases even more, with an average disability of twelve weeks' being the time offered by the Standard Accident Insurance Company as a cash settlement at the time of the accident. Heilfrich, in his book on fractures published in 1900, gives an average time for healing as thirteen and one-half months, with 34 per cent. able to work and 66 per cent. unable to work. In view of these facts I report the following case:

April 6, 1901, Mr. A. G. B., age 34, married, weight 205 pounds, height 6 feet and 1 inch, sustained a fracture of the left femur while bowling, caused by muscular contraction in the effort to throw the ball. The fracture was complete, there being free mobility at the point of injury. Little care was used in moving him to his home, and as a result the tissues surrounding the fracture were very much mutilated. The ecchymosis and extravasation that followed involved the limb from below the knee to the crest of the ilium. Forty-eight hours after the accident the circumference of the injured limb at the junction of the middle and upper third was fourteen inches more than the right one at the same point. The amount of fluid at this time about the knee joint was enormous. In fact, the whole picture of the injured limb at this time was of as severe an injury as I have ever seen of a thigh, barring one requiring an amputation. Dr. Buford, who examined the limb at this time, confirmed the severity of the injury. On the third day after the accident, with the assistance of Dr. J. G. Hughes, a pneumatic splint was applied. the limb was measured and showed one and one-half inches of shortening. It was impossible at this time to get complete extension because of the great swelling. A gentle massage of the limb was kept up at frequent intervals; which was easily done while the splint was on. By the fifth day the swelling had subsided enough so that the foot was brought down in perfect position.

Twenty-four hours after the application of the splint, the patient was free from pain, and could move himself about in bed with perfect ease. Two weeks after the application of the splint he was about the house. The next week he was going about the street, and in less than four weeks after the application of the splint he was at his office; he was sleeping without his splint, and was able to get into a bath-tub unassisted. Measurements made by Dr. W. H. Vary, Dr. J. G. Hughes, Dr. Ochsner and the author, show that there is no shortening in the injured limb.

The following advantages are gained from experience with the pneumatic splint: 1. It can be applied without assistance. 2. Fractures can be reduced without an anesthetic. 3. Patient can move about freely in bed, after its application. 4. Gives free access to compound fractures without removal of splint. 5. Reduces the time of disability over one-half by American report. 6. Prevents shortening. 7. Prevents angular deformity. 8. Changes our pathology. 9. No complete circular constriction to impair the blood supply to the limb. 10. Massage can be given to the entire limb without removing the splint.

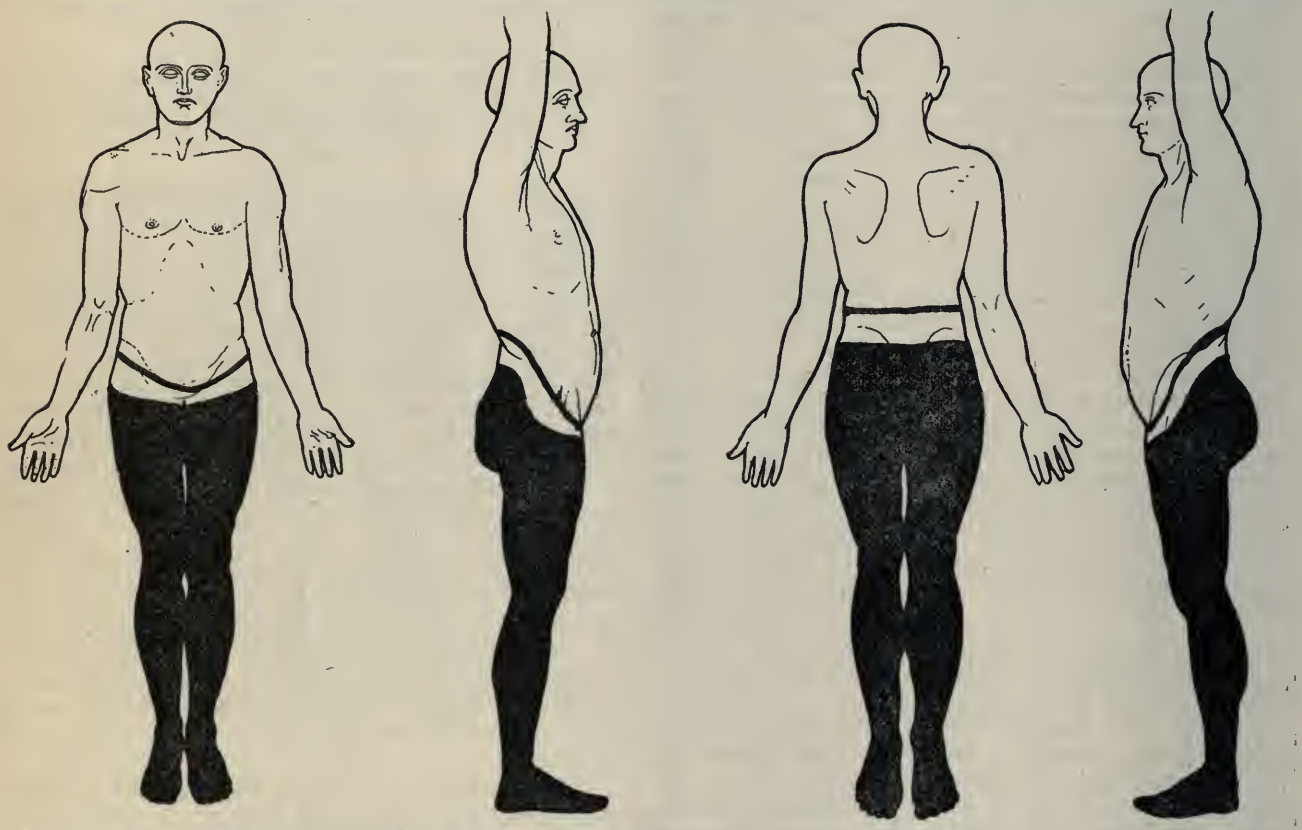
* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: W. J. Mayo, H. O. Walker, and A. J. Ochsner.

REMARKS ON THE TRAUMATIC NEUROSES.

HUGH T. PATRICK, M.D.
Professor of Neurology, Chicago Policlinic; Clinical Professor of Nervous Diseases, Northwestern University Medical School; Neurologist to the German, Maurice Porter, Passavant and Wesley Hospitals, Etc.
CHICAGO.

I think we are agreed in understanding traumatic neuroses to mean functional disturbance of the nervous system caused by traumatism. In the present state of society this traumatism is generally accidental. We are doubtless also agreed that in the symptomatology of the traumatic neuroses there is nothing pathognomonic of injury by violence and that a case of traumatic neurosis generally presents a picture of hysteria, neurasthenia or hypochondria, or, what is more frequent, a combination of two or all three of these neuroses. A certain admixture of melancholia is far from rare.

In the diagnosis of any neurosis the most essential step is not the recognition of a neurosis, but the exclusion of organic disease. For this a single examination will not always suffice, as a combination of the two is very common, and the former may so obscure the latter as to make its prompt and positive recognition impossible. Sometimes it is exceedingly easy. When organic change is undeniably present, it is still important to determine the presence of functional trouble, as this must necessarily have great influence on prognosis and treatment.



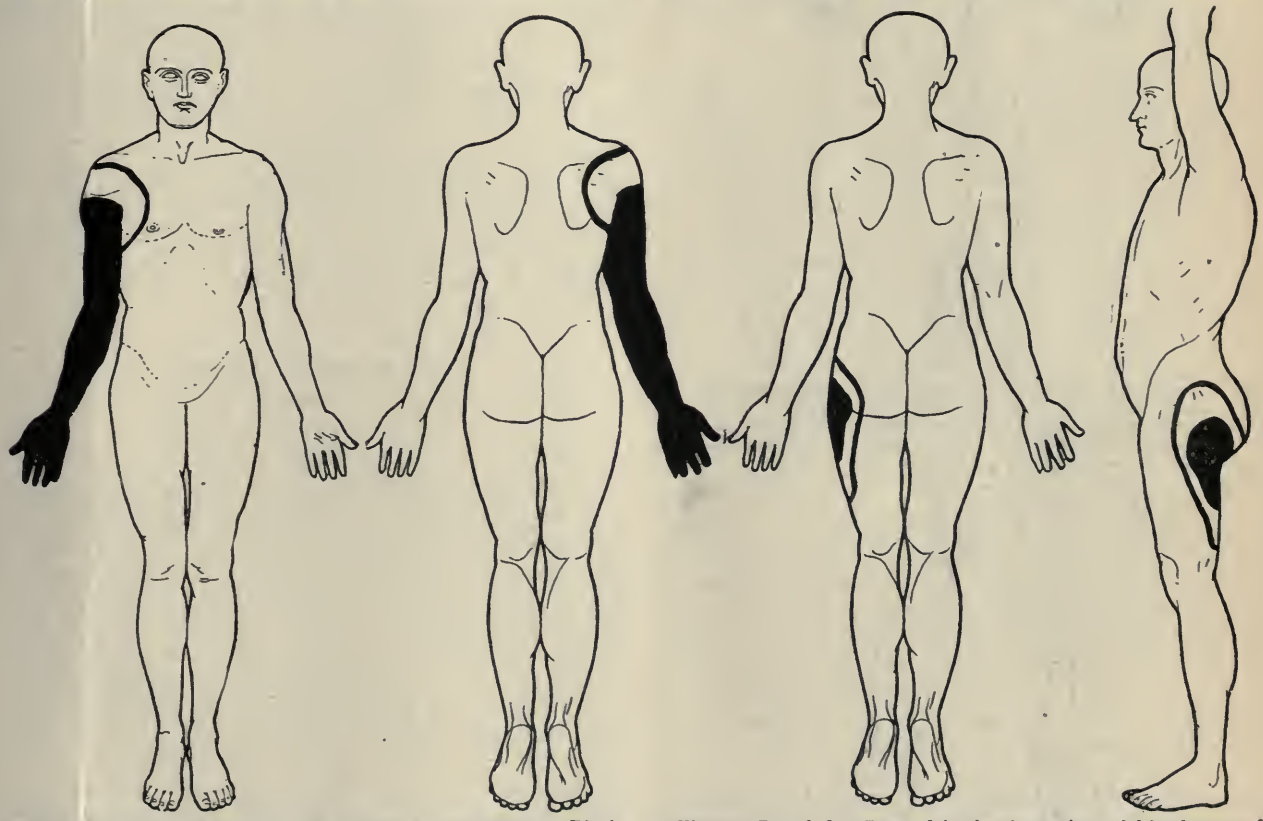
In my experience incorrect diagnoses are ordinarily made because of failure to recognize: 1, that pain, tenderness, paresis or paralysis, hyperesthesia, anesthesia, incoördination, tremor, dizziness, tachycardia, syncopal attacks, vomiting, loss of weight even to emaciation, impaired speech, convulsions and poor vision, are not necessarily indications of organic disease, no matter how continuous or how long continued the symptoms may be; or 2, that atrophy, reaction of degeneration, incontinence of urine or feces, retention of urine (generally), loss of deep reflexes, bedsores, Babinski's sign, ocular or facial paralysis, optic atrophy or neuritis, hemianopia, glossy skin, rapid (five or six per second) and uniform ankle clonus, impaired pupillary reaction, semi-erection of penis, and anesthesia corresponding exactly to a peripheral nerve or spinal segment, indicate organic disease.

In addition, it may be remarked that the nature and general extent of an accident, presence, absence or location of external lesions and even the duration of unconsciousness are most unreliable data upon which to base a diagnosis.

There are certain symptoms which demonstrate beyond a peradventure the presence of functional disease. They are, on the whole, such signs as belong to hysteria, the symptoms of neurasthenia and hypochondria being so purely subjective as not to be demonstrative. The catalogue of these distinctive traits is rather long and I shall take time to speak of only two, as they may be elicited at a single examination and their purport grasped even by a layman.

1. The anesthesia or hyperesthesia of a traumatic neurosis may ordinarily be shown to be limited by a sharply-cut border. On anatomical grounds this is impossible in organic affections. The distribution of one sensory nerve always encroaches upon the territory of the adjoining nerves. Obviously, then, when sensory nerves are paralyzed, the transition from anesthetic to normal area will be more or less gradual. This overlapping of sensory supply applies even to the two halves of the body, the nerve filaments of one side crossing the median line a short distance. Hence, in hemianesthesia from organic disease, some impairment of sensation is demonstrable beyond the middle line, while, on the anesthetic side, sensation is better close to the median line. In nearly every organic case it is impossible to determine exactly where anesthesia ends and normal sensation begins. In functional disease, the distance between complete anesthesia or analgesia and normal sensation is often no more than 1/16 or 1/32 of an inch. To bring this out, considerable care and patience are sometimes necessary, but, once demonstrated, the proof of functional disease is conclusive. Naturally, the patient must not see the procedure. The best way is to touch or prick alternately the anesthetic (or analgesic) area and the normal surface, at first wide of the dividing line, then closer, finally narrowing the distance down to the minimum. It is astonishing how close a pin prick which is not felt at all may be to a line where sensation is perfect. The demonstration is often facilitated by a little suggestion; for instance, using throughout the examination the expressions "up there" and "down here," or "over there" and "over here" to convey to the patient the idea that the pricks or touches are considerably separated, even when they have become very close together.

2. The line of demarcation between normal sensation and anesthesia rapidly shifts. This demonstration also requires a little care. The border line having been definitely determined (of course, unseen by the patient), it is lightly marked with a pencil, and the examiner directs his attention elsewhere—to heart, lungs, eyes, etc., for five or ten minutes. He then returns to the anesthetic region, the patient still blindfolded, and repeats the former examination for determining the limit of the area. Or he may locate it by simply approaching it by slow, successive touches or pricks rather close together. The dividing line will still be found to be sharply defined, but to have moved one to six inches from its former location. Evidently such shifting can occur only in functional disease. Figures 1 to 10 are taken from illustrative cases.



Figures 1 to 4.—Case of general shaking up and bruise of back in railway accident. Black indicates area of complete anesthesia and analgesia. Line indicates extent to which border shifted within ten minutes.

As before stated, these two striking traits of functional sensory disorder pertain to hyperesthesia as well as anesthesia and are particularly useful in the examination of the tender backs or spines so very frequent after accidents. The tender spot or the extent of a tender stretch is exactly located, defined and marked. After ten minutes or more the back is re-examined. The observer begins at the upper or lower end of the spinal column and with a finger or rubber-tipped pencil, progresses downward or upward, as the case may be, pressing successively over the spinous processes as he proceeds. In due time he reaches the tender ones, but they are not where they were. That is, they are not the same ones.

Let us suppose that the first time the 8th, 9th and 10th dorsal spines were tender; it will now be the 6th, 7th and 8th, or the 10th, 11th and 12th. Sometimes the shifting is much greater than this. In any event, it shows that the tenderness is purely functional and not caused by injury of the spinal cord, membranes, nerve roots, vertebræ or ligaments.

I can not too earnestly insist upon the importance of an early and positive diagnosis, because then may be early instituted the correct treatment. Prompt and proper treatment is quite as important in functional as in organic cases. A traumatic neurosis is never produced complete and at once by an accident. It were as natural for people to be born like Athene springing from the head of Jove perfect in the plenitude of her powers. Hysteria is never born—it develops; neurasthenia can not be produced in a day; hypochondria is a thing of growth, and a traumatic neurosis is always the product of evolution. Once evolved, it is a hard-grained

Figures 5 and 6.—Case of injury to arm by machinery. Black indicates anesthesia, and line the extent to which it shifted during examination.

Figures 7 and 8.—Case of bruise in region of hip from a fall. Black indicates area of hyperesthesia; the line shows border of hyperesthetic area a few minutes later.

disease, difficult to manage and often of serious prognosis, but if detected in the germ the growth may be effectually checked and the patient saved years of suffering.

The mere fact of accident or injury never of itself causes a neurosis—be the injury of whatsoever part of the body, and be it fracture, dislocation, laceration, burn, scald, scratch, contusion, hemorrhage, strain, sprain, electric shock, or that much abused, indeterminate derangement called concussion. To the physical ictus of a traumatism is nearly always added a simultaneous mental shock, but of vastly greater effect than this are a thousand and one autopsychic and heteropsychic influences. Nothing short of painstaking study will reveal the countless multitude and immeasurable effect of these little forces. To a well-balanced and normally indifferent person it is almost incredible how often and how intensely one of these patients will repeat to himself the possible consequences of a trifling injury; how he will review all the minutiæ connected with the accident and as minutely scan the future; how he will scrutinize, classify, analyze and synthetize his symptoms. Equally remarkable is the weight he gives to the opinions and advice of his lay friends, and even to the literature of almanac and quack advertiser. Not at all remarkable is the importance attached to the dictum of his physician, but most remarkable is the fact that all his observations, all that he hears and all his conclusions tend to make him worse and to convince him of the gravity of his condition. All this, slowly or rapidly, in accordance with his plasticity, educates him into an abnormal condition. Pretty soon this process of educational evolution becomes automatic, subconscious if you please, and with this stage is already reached the stage of difficult treatment. When the patient says, and thinks, that he has got the accident pretty well out of his mind, that he is trying to "throw it off," that it might have been worse; when he tends to make light of some of his symptoms, but always mentions them; when he makes strenuous efforts to overcome trifles; when he settles into a cheerful resignation; when he does these things but fails to improve, we may be sure that in his innermost consciousness the conception of irreparable injury is ever with him and is slowly crystallizing him into a state of invalidism.

In this connection I need only mention the diabolical effects of litigation, particularly deferred or prolonged litigation. Not only is the patient compelled to specify every pain, distress and disability, and to do this repeatedly, but he must hear the recital of witnesses as to the dire disaster and its deplorable effect upon him. Under the circumstances it is only human nature to emphasize, not to say exaggerate, all symptoms. Furthermore,

he, his friends and lawyers instinctively combat any circumstance or statement tending to minimize his suffering. And finally, he is taught and teaches himself to look upon the future as one long valley of the shadow of death, ending only in death itself, for on the blackness of the future depends the brightness of the verdict.

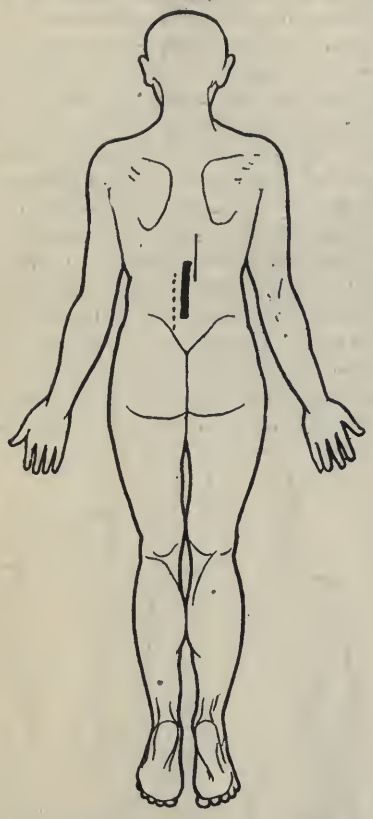


Figure 9.—Case of general bruising—thrown from buggy by collision. Heavy line indicates tenderness along spine. Light line indicates same when examined from below upward; dotted line when examined from above downward. Light and dotted lines are to be thought of as occupying the median line.

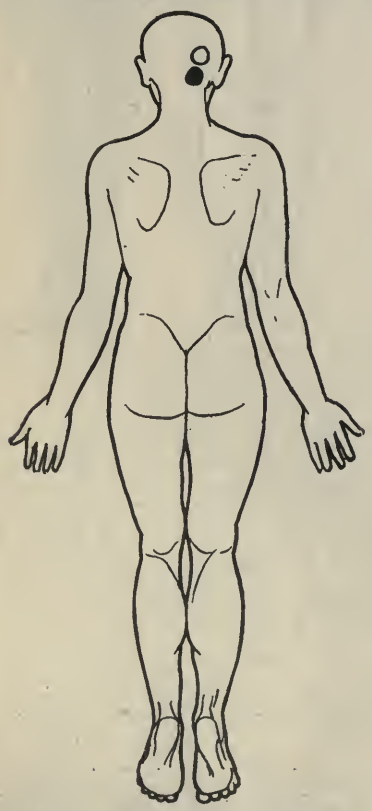

Figure 10.—Case of railway accident. Black spot indicates location of excessive tenderness, circle shows place to which it shifted within a few minutes.

How important, then, is the prophylactic treatment of these poor people. They are to be protected from ignorant doctors, foolish friends, designing lawyers and their susceptible selves. It is our duty—since it is generally within our power—to give them this protection; protection from ignorance by being not ignorant; protection from friends, first by perfectly understanding the case, then by clear and positive statements to the patient, and, last, by preventing or combating the officious suggestions of meddlesome well-meaners; protection from litigation by promoting prompt and definite settlement; protection from the patient himself by getting him out and at work as soon as possible, by begetting a wholesome and cheerful frame of mind and by getting the accident and all that pertained to it completely out of his life.

Because of the foregoing, in every case in which the question of "damages" arises or the possibility of litigation is present, the physician should advise both sides alike to make an immediate and final settlement.

A consideration of the treatment of the fully developed neuroses would carry me quite beyond a reasonable time limit. The proper methods to be employed may readily be inferred from the foregoing remarks and from our knowledge of the best means of handling the fundamental neuroses, but the successful employment of these methods requires the utmost tact, patience and energy—in short, the finest of medical technique.

34 Washington Street.

NOTES ON SMALLPOX.

S. L. JEPSON, M.D.
EX-HEALTH OFFICER.
WHEELING, W. VA.

I can not believe that there are many physicians who any longer entertain a doubt as to the genuineness of the mild smallpox that has prevailed to so general an extent during the past two years. The many valuable papers on this subject recently printed in THE JOURNAL should convince even Dr. Happel, whom we may honor as the leader of the doubters, and whose papers have no doubt led many inexperienced physicians into error.

Having served for eleven years as Health Officer of Wheeling, and observed several hundred cases of smallpox of every possible variety, and through a period of nearly thirty years, I wish to give my opinion, in the most emphatic way possible, that our recent smallpox, of which this city has had about eighty cases, was no new disease. In every outbreak of smallpox extremely mild cases occur, cases that are atypical and calculated to deceive physicians of limited experience. In the recent epidemic there occurred very many such cases, very few typical ones, and some unusual varieties, which defied positive diagnosis by the most experienced, unless watched closely for days. In my experience these most resembled varicella; but whereas the vesicles of varicella dry up in four or five days at most, that of even these mildest cases of smallpox ran a course at least twice as long.

Last November smallpox was brought to this city by colored convalescents from an infected camp of men working on a new railroad near Clarksburg. Within a few days fourteen colored men were taken down with it, all of whom contracted it from the same origin, in a saloon and gambling room conducted by a colored man, and patronized almost exclusively by colored men. All

were treated by me in the Municipal Hospital. Not one had ever been vaccinated, and yet there were all grades of severity exhibited. One man was in the hospital but six days, and was dismissed within ten days of the first appearance of the eruption, not having more than twenty vesicles on his whole person. Had this been an isolated case no physician could possibly have made a positive diagnosis, unless the history should have determined it. Yet in this same group of cases there was a confluent case, with a temperature of 108.5°, observed by myself at 4 p. m., and by the nurse at 8 p. m., taken in the mouth with a thermometer whose correctness I have verified. This patient recovered. Later I had a hemorrhagic case, which recovered. Were these last two cases variola vera? Even Dr. Happel would say, "Yes." So, therefore, were all the others, which represented all degrees of severity, although nearly all were very mild.

How was it in other localities? Called 70 miles away to determine the nature of an eruptive disease in an infant, I found a well-marked case of smallpox concerning which two physicians had differed; one called it chicken-pox, which it in no way resembled. A week later it proved fatal, and both parents contracted smallpox.

Dr. A. Wilson and myself were called to a mining town in Ohio, to determine a dispute between physicians and advise concerning an outbreak of an eruptive disease. We were taken to the house of one miner lying dead, after an illness of but three or four days. The appearance of the body and the history of the case left no doubt that the man had died of malignant smallpox. On the street we met another miner, just from his work in the mines, with an abundant variolous eruption, at about the tenth or eleventh day, and yet never ill enough to stop work for a single day. We found that fifteen cases had occurred, a number of the patients adults, and all had passed as varicella until a death aroused suspicions. Did the dead man have variola vera and all the remainder have varicella? A number of these cases were typical in appearance, although quite mild. In over thirty years' practice I have seen but one case of chicken-pox in an adult. I therefore hold that any acute eruptive disease in the adult that in any way resembles either chicken-pox or smallpox, should receive the same sanitary care as the latter disease, until its true nature is determined by close observation and time.

My observations here lead me to the conclusion that but little infection attends these very mild cases of smallpox. The primary fever is mild, sometimes passing unobserved; the secondary fever is often absent, and in many cases the eruption is very sparse, and it dries up without passing through the usual stages. As a consequence, a patient is less apt than in severe cases to convey the disease to exposed persons. Otherwise this city must have had hundreds of cases, for a number of patients strolled through our streets, frequenting saloons and other crowded resorts, for two to ten days after the eruption appeared. One man slept in a family of five, three of whom were unvaccinated children, for eleven days after the appearance of the eruption, and spent every evening at a social club-house. Not a single case resulted. One colored barber shaved his patrons for two days, and another for five days after the eruption appeared, and no case resulted. It is scarcely possible that all persons thus exposed had been vaccinated.

Only one of my patients made any claim to having been vaccinated, and I found no evidence of it in this case, one of my worst, which was in the hospital four weeks.

But one death in 76 cases occurred, and this patient was an infant. Why were the cases so mild? Dr. Hyde, in his paper in *Popular Science Monthy,* expresses the belief that the mildness of the cases in our recent epidemic was due to an immunity acquired by our people by inheritance, several past generations having been vaccinated. His own language is: "When it (the smallpox) gathered to itself the added power by which it was enabled to spread from community to community, its extension was not through a population virgin of protection by previous vaccination, or the children of the vaccinated." That a degree of immunity may be conferred by inheritance I am not prepared to deny, although this theory would be difficult to prove. The facts in reference to our recent epidemic can not be correctly held to support it in any way. After this smallpox entered the country from Cuba, it extended rapidly through the former slave-holding states, attacking chiefly the colored race, many thousands of whom were its subjects. These colored people in this city and state, and I think all through the South, are emphatically "virgin of protection by previous vaccination." Neither the present nor past generations of them have been vaccinated at all generally, and hence there was no modifying influence by inheritance. And yet, so far as my personal observation extended, the cases were quite as mild in the colored race as in the white. My very mildest case was in an unvaccinated black man.

Again, if there has recently been any such modifying influence by inheritance, as Dr. Hyde claims, it should have shown itself just as distinctly five or more years ago. But such was not the case. In 1895 and 1896 nearly 300 cases of smallpox occurred in this city and vicinity, but the cases were by no means of such mild type as those recently observed, and quite a number of deaths occurred.

No one has yet satisfactorily accounted for the mildness of our recent cases of variola. Has any explanation been presented of the recent mildness of typhoid fever, diphtheria and scarlatina? I am quite sure that none of these diseases occurs in this locality with the same virulence as in former years. No inherited modifying influence can account for this fact, and I think we will have to search further before we can explain why our late smallpox has been so mild.

As a sanitary officer, I have encountered much opposition to vaccination, not a few parents withdrawing their children from the public schools rather than have them vaccinated. In view of this fact, which is true of every community, and considering the very little suffering and very low mortality from smallpox at present, I have very seriously doubted the wisdom of communities going to great trouble and expense in the sanitary care of this disease, virtually to protect a limited number of ignorant or bigoted persons. The mortality has been nowhere greater than 2 per cent., which is much less than that of whooping cough, the suffering from which also is so great. We can do little, and we actually do nothing, to limit the spread of the latter. Why interfere with the former, against which each family can with certainty protect itself by vaccination?

Permanganate Treatment of Noma.—A. A. Kissel reports most encouraging success with local treatment of noma, supplemented by exceptionally nourishing food and strict hygienic measures. The lesion is curetted and then irrigated with a hot solution of potassium permanganate, concluding by dusting with iodoform. His statistics published in *Khirourgia,* x, 56, confirm the benefits of this treatment.

SATURDAY, DECEMBER 14, 1901.

A QUESTION OF PRIORITY.

We are reasonably deferential to European medicine in this country, and it may be at times unreasonably so. A few noted advances in surgery have been credited to us, such as anesthesia, certain matters in abdominal surgery, etc., but as a rule only after controversy and the refutation of the assertions of the aggressive European claimants and their partisans. Brown-Séquard used to complain that Germans were constantly rediscovering French contributions to science, and in this country we may with some reason hold all Europe in a like way, as trespassing upon our own preserves of credit for additions to surgical methods and advances. One of the latest of these is to be found in Mr. Buckston Browne's article in the London *Lancet* of November 23, abstracted in this issue, in which he claims suprapubic prostatectomy as peculiarly a British contribution to surgery and gives all the credit of its origination and introduction to a British surgeon, McGill, suggesting, therefore, that it be henceforth called by his name. A review of the history of the operation shows that the removal of a prostatic obstruction to urination in an elderly man through a suprapubic incision was first performed by Dittel in Vienna in 1885, though several years earlier Billroth had removed a large myoma from the bladder of a boy by the same route. Dittel's incision was made for drainage, not for prostatectomy; the operation was not repeated by Dittel, though he did on subsequent occasions "decapitate" a middle lobe as an incident in suprapubic lithotomy. Dittel's patient died on the seventh day.

Belfield of Chicago attacked the prostate through a perineal incision in 1885; at the autopsy of a case successfully operated seven months earlier, he found that the obstruction was a tumor which could have been readily removed by suprapubic cystotomy—a fact which, he says, "induced the adoption of that incision in subsequent operations." Accordingly in June, 1886, and again in October of that year, he made a suprapubic cystotomy for the purpose of removing prostatic obstacles to urination, making a complete success in the second patient. These were unquestionably the first suprapubic prostatectomies ever planned; both were executed and recorded in society transactions[1] before the operation had been performed by anyone else, excepting only the Dittel case above mentioned.

In September, 1886, Kummell in Hamburg attempted to destroy prostatic outgrowths by sinking the cautery into them, operating through a suprapubic incision; and some months later he removed a prostatic tumor by the same route. McGill in Leeds made his first suprapubic prostatectomy in April, 1887, removing a tumor as large as a bean; upon his experience with three cases, he advised the operation as a routine measure—advice which Belfield refrained from giving. Belfield, however, stated that the suprapubic incision was often insufficient and advised the addition of the perineal boutonnière as a means of access to the prostate.

The work of McGill and his colleagues at the Leeds Infirmary was certainly the chief agency in calling the attention of surgeons to the feasibility of suprapubic prostatectomy. But when Mr. Buckston Browne calls it an "English operation" and "McGill's operation" he appears as an attorney urging a partisan argument rather than as the recorder of surgical progress. The operation was first advised, deliberately planned, and successfully executed by Belfield of Chicago and as the logical result of previous experience in perineal prostatectomy.

There are good reasons against the application of the names of individuals to a special operation or disease, not the least of which is the multiplication of synonyms which it entails through national or local pride. Some disorders like exophthalmic goiter thus carry three or four names in as many different countries. With this general objection there is a special one of injustice in attaching the name of McGill to the suprapubic operation of prostatectomy. If the operation must have a name it should be that of Belfield, who rationally conceived, carried out and published the method before anyone else. Dittel's operation was an accident.

ON THE EXISTENCE OF PATHOGENIC AGENTS TOO SMALL TO BE SEEN.

Studying a destructive epidemic disease among chickens, Lode and Gruber[1] of Innsbruck made the observation, which was confirmed by frequent repetition, that the specific cause, whatever its nature may be, passes through Berkefeld or Chamberland filters. Filters of this kind, it is well known, keep back all bacteria that are visible with our present means of magnifying microscopic organisms. A few years ago Loeffler and Frosh showed that the virus of foot and mouth disease also passes through such filters, the filtrates being virulent. Recently Beijerinck has demonstrated that the cause of a disease that produces spots on tobacco leaves is a contagium that passes through porcelain filters. In these interesting cases two possibilities have been considered: Either the apparently sterile filtrate contains in solution an unusually active poison or the unknown agent is so small that it passes through the pores of a filter that retains the smallest visible known

1. Centralbl. f. Bacteriologie, 1901, xxx, 593-604.

bacteria. The first possibility seems to be excluded in the case of the disease described by Lode and Gruber because of the repeated reproduction of the disease experimentally in a series of animals, indicating that the cause is one capable of multiplication. Here at least the assumption that the agent is so minute as to pass through the pores of the filters seems the more reasonable. Abbe of Jena has calculated that elements only one-tenth to one-fifth times smaller than the smallest known bacterium, the bacillus of influenza, fall below the range of visibility with the most perfectly constructed apparatus for magnification now made. As pointed out by Lode and Gruber, this second assumption is not free from difficulties. The pores of the filters are in reality much larger than the bodies held back. The real factor at work is attraction, and it seems peculiar that it should fail to operate when the limits of the visible is reached.

If there are several pathogenic organisms that possess the power of passing through porcelain and similar filters, it would be quite reasonable to assume that there exist in nature innumerable saprophytic and other forms of similar character. But of such forms we know absolutely nothing, although it might be expected that they would have made their existence known by the formation of deposits, pigments, gas and other products in the fluids which are passed through the filters and then remain free from bacteria as far as known. If these mysterious serums pass through filters it would seem to indicate that they exist in a different form from that of the ordinary, dense bacterial bodies, perhaps as semi-fluid protoplasmic masses. Lode and Gruber also suggest that in these instances the virus may be not corporeal in the ordinary sense, but a substance in solution and nevertheless endowed with the power of reproduction, which acts somewhat after the manner of enzymes and is not thereby itself consumed. But it is difficult to comprehend such substances because we are unable to compare them with known analogues. Of course it lies near at hand to offer the suggestion, as has been done before, that other diseases of infectious character but unknown cause, such as syphilis, measles, smallpox and carcinoma, are also caused by organisms which hitherto have escaped observation because they are too small to be seen. The existence of diseases of this character among animals, with which it is comparatively easy to make experiments, will undoubtedly prove to be of great aid in solving the important problems suggested in the foregoing.

THE TOE PHENOMENON OF BABINSKI.

Slight irritation of the sole of the foot is ordinarily followed by plantar flexion of the toes, particularly the four smaller; while with more marked irritation transitory plantar flexion is followed by dorsal extension, particularly in the great toe, associated with flexion of the foot, leg and thigh, and at times also of other muscles. Under certain abnormal conditions it has been found, particularly and earliest by Babinski, that slight irritation of the sole of the foot causes not plantar flexion, but dorsal extension. Under such circumstances lesions of the pyramidal tracts have almost always been found and the symptom has been considered pathognomonic of this condition. The phenomenon has, however, been observed also in connection with epileptic seizures, in cases of strychnin poisoning, in other diseases attended with exaggeration of the reflexes and also in healthy infants; while, on the other hand, it has been found wanting in cases presenting undoubted pyramidal lesions. In explanation of this reflex it has been suggested that, as a result of a lesion of the pyramidal tract, fibers are damaged that normally inhibit the action of the extensors that takes place in association with that of the flexors on irritation of the sole of the foot.

For the purpose of clearing up a number of disputed points in connection with this subject, Dr. Herman Schneider[1] undertook a study of the toe reflex in a large number of cases of various forms of disease of the nervous system and as a result of this investigation he concludes that the normal movements that occur in response to irritation of the sole of the foot are the result of two reflexes, having different seats in the central nervous system. The one, consisting in isolated plantar flexion upon slight irritation, is a cortical reflex, while the other, consisting in dorsal extension of the toes, with combined movement in the leg, on active irritation, is a spinal reflex. Failure of plantar flexion on slight irritation, with dorsal extension of the toes—that is, preservation of the spinal reflex—constitutes the Babinski sign. That this can be induced with much greater facility than normally is invariably dependent upon general exaggeration of the spinal reflexes.

The Babinski sign may be developed by interruption of the pyramidal tract, with resulting abolition of the cortical reflex. This interruption may also take place at the beginning of the tract in the motor cortex, as in cases of epilepsy. Normally, only the varying degrees of irritation necessary for the development of both reflexes allow of their differentiation. If in consequence of general exaggeration of the spinal reflexes—as by strychnin, diseases attended with exaggeration of the reflexes without a pyramidal lesion—or of conditions that increase the difficulty of developing the cortical reflex, such as mental diversion, stupor, edema, the spinal reflex can be developed as easily as the cortical reflex, or more easily, the latter may be suppressed by the dynamic preponderance of the former and appear to be entirely wanting. In this way a typical Babinski sign may be developed in the absence of a lesion of the pyramidal tract, by varying the exciting factors of each reflex. It is not possible to separate with certainty this Babinski sign attended with suppression of the cortical reflex from that associated with destruction of the cor-

1. Berliner Klin. Wochenschrift, 1901, No. 37, p. 946.

tical reflex. It is also not possible in the presence of general exaggeration of the reflexes to make a diagnosis of a pyramidal lesion from the presence of the Babinski sign alone. On the other hand, persistence of this sign without destruction of the cortical reflex is rare; a single plantar flexion in the midst of a series of dorsal extensions excludes a true Babinski sign, and as the true Babinski sign is frequently, almost always, associated with a lesion of the pyramidal tract, the sign can be employed practically as a means of differentiation between the lesions of the pyramidal tract and clinical conditions simulating them.

TYROSINASE, A FERMENT PRODUCING A PIGMENT RESEMBLING MELANIN.

When the freshly drawn juices of certain plants are allowed to stand for a short time exposed to air their color turns to an intense black. It is by such a process as this that the lacquers used in oriental countries are produced. Bertrand found a few years ago that this change in color is due to the action of an oxidizing ferment, laccase, upon a substance that is oxidized with great readiness, laccol, and which is chemically a member of the aromatic series. Laccase has since been shown capable of oxidizing many other aromatic substances. Similar oxidizing ferments seem to be present in many and varied forms of plants, among them the mushrooms. In mushrooms Bertrand found, besides a ferment resembling laccase, one whose oxidizing power was limited to a specific action on tyrosin, and therefore called tyrosinase. Beet roots and the dahlia also contain tyrosinase.

Otto v. Fürth and Hugo Schneider[1] have recently investigated the occurrence of tyrosinase in the animal kingdom, and the relation it bears to the production of melanin. It was found to be a regular ingredient of the hemolymph of insects, and probably explains the darkening of the juices of such animals when exposed to air. In the blood of certain crayfish a similar but less active ferment was found. Most interesting was the observation that the lining membrane of the ink sacs from which the cephalopods throw out their inky secretion, is able to produce a black color when placed in a solution of tyrosin. A chemical study of the black pigment obtained by allowing tyrosinase to act upon a solution of pure tyrosin showed it to correspond in many respects to the ordinary melanins. Most important in the eyes of these investigators is the fact that the ratio of the carbon, hydrogen and nitrogen in this artificial pigment is the same as the ratio of the same elements in the group of pigments usually considered as melanins, including the black pigment of hair, skin, choroid and melanotic tumors, the sepia pigment of cuttlefish, and also the artificial pigments produced by decomposition of proteids. They suggest that tyrosinase is present wherever pigments are found in the tissues, and that the pigments are produced by action of this ferment on tyrosin. They account for the presence of tyrosin by the observation of Salkowski that tyrosin is one of the products of the self-digestion of tissues. Hence, in the production of melanin a double ferment process may occur; by an autolytic ferment an aromatic substance is derived from proteid, and this substance is converted by the tyrosinase into melanin. Against this simple explanation we must place the following fact: All analyses have shown that these various melanins, with the single exception of that from the choroid, contain sulphur in considerable proportions, as high as 10 per cent. in some cases. As tyrosin contains no sulphur it alone can not be the source of these melanins. This difficulty seems not to have occurred to v. Fürth and Schneider. However, the entire subject of pigment formation is so obscure that these observations are of greatest interest, and that so resistant and unalterable a substance as melanin can be produced by a ferment is in itself striking. In addition, it illustrates the wide possibilities of the newly reopened study of enzymes and their activities.

1. Beiträge z. Chem. Physiol. u. Pathol., 1901, I, 229.

PHYSICAL CULTURE AND MEDICINE.

At the present time perhaps more than at any former period in our modern civilization the public has grasped the idea of physical culture and its advantages. The notion that symmetrical development of the body is a safeguard against disease and a cure for existing disorders is widespread and, as Dr. Newman points out in a recently published paper,[1] is being exploited in all quarters as the grand cure-all to the disparagement of drugs and doctors. The injustice of it is, as he says, that so broad a truth, taught for so many years by our profession, should just now "be hailed as a new discovery and the credit given to mercenary outsiders." The fault is nevertheless largely our own; while we have prescribed exercise, massage, etc., in a general way we have left the details and even the oversight of them to others as unworthy of our attention. In this we not only sacrifice our own interests but those of our patients by allowing them to fall into the hands of those who, while recognizing a valuable principle that we too much ignore, are yet too ignorant and narrow to be of use in the times of real danger. Medicine suffers in public estimation and gross quackery thrives, as anyone can see by scanning their advertisements and the special publications of these extra medical practitioners. It is high time, as Newman says, that the medical profession gave more attention to the physical education and development of the patients and practiced its methods. The public has the notion that the practice of medicine is merely the giving of drugs and there is danger of this getting into our laws through ignorant judicial decisions and exceptions in the legislative enactments regarding the practice of medicine. This popular delusion should be counteracted by the general utilization by

1. Plexus, November, 1901, pp. 223-228.

our profession of whatever is scientifically and therapeutically of value in every method of physical training. We should not merely recommend physical exercises, massage, etc., but should follow up our advice and see that these are administered according to our recommendations and by operators in whom we can depend if we have to trust them out of our own hands.

It is not as a business proposition that these recommendations are made; the medical profession is, as the author of the address quoted puts it, about as money-wise in its practice "as would be a liquor-dealers' association for the promotion of total abstinence;" it is a part of our duty as guardians of the public health and as upholders of scientific truth against the attacks of charlatanry and general dangerous impositions. We should equip ourselves with every aid for this grand work, and while the advice here quoted was given especially to those starting out in their medical careers, it is none the less suitable to many others who are not yet too old to learn. A further suggestion made is that there should be thorough instruction given in all departments of physical culture in medical schools, so that the graduate can not only know how to personally direct treatments, but to instruct his patients in what is safe and advantageous to be left to them to do, and it is none the less worthy of being adopted. It is to be hoped that the time will come when this suggestion will be thoroughly followed out by all our medical colleges.

FEEING THE NURSE.

Evidently things are getting in bad shape in England, if we are to believe the statement made by a correspondent in a recent number of *The Lancet*. There are rumors that there is a division of the fee among some of the members of the profession here, but this division is between the surgon or the consultant and the family physician of the patient. On the other side, however, they seem to have gone one better and a division of the fee is made with the nurse. According to the correspondent, certain medical men over there are paying sums from a shilling to half the confinement fee, or more, to the nurses in attendance, who, to use their own words, make their living from "following the doctors." This tipping of the nurses is done with the hope that the recipient of the fee will recommend the doctor to future patients and, in other words, act as his drummer. As *The Lancet* editorially comments, the probability is that things are not quite as bad as this correspondent makes them out to be, even in England, where tipping is such a common every-day and every-where affair.

AWARDS OF THE NOBEL PRIZES.

Of the five awards of the Nobel prizes four are of interest to the medical profession, namely, the award to Dr. Henri Dunant, originator of the Red Cross; that to Professor Roentgen, discoverer of the *x*-rays; that to Van't Hoff, the chemist, and that to Behring for the discovery of antitoxin. No one will contest the merits of the first, nor of the second and third, though Roentgen's discovery was an accident and had been very nearly achieved by other scientific workers. It is a pity, however, that the award for the discovery of antitoxin had to go to one whose scientific and medical merits are marred by the unscientific and commercial spirit that led him to seek exclusive patent rights for his discoeries. Had Kitasato, his co-worker and co-discoverer, been remembered, it would have given more general satisfaction to the medical profession. Van't Hoff, it will be remembered, was in this country last spring and delivered a course of lectures at the University of Chicago, receiving at the same time the degree of LL.D. from that institution.

THE ETIOLOGY OF HAY FEVER.

The popularly accepted theory of the etiology of hay fever places the responsibility for this annoying disease upon vegetable pollen. The exact manner in which pollen causes hay fever does not seem to be cleared up. Recent investigations by Heymann and Matzuschita[1] are calculated to throw some doubt upon the correctness of the pollen theory, because in a careful examination of the nasal contents of several hay fever sufferers, they failed to find much if any pollen present. They point out further that in certain experiments by Blackley and others only temporary irritative phenomena were induced by the introduction into the nose of much larger quantities of pollen than ever can take place under natural conditions, because the quantity of pollen in the air at the most suitable season and in the most suitable places is not very great. Heymann and Matzuschita made the observation that the number of streptococci in the nasal secretion of hay fever patients greatly exceeds that in the secretion of normal persons. Often streptococci were present in pure cultures in the case of hay fever sufferers. Now, the bacteria found upon pollen in nature did not at all support the plausible inference that pollen might serve as the carrier of the streptococci; for streptococci were never found on free pollen. While there are not enough data on hand to permit the assignment of an etiologic rôle to the streptococci found in the nasal cavities of hay fever patients, these observations certainly tend to compromise the pollen theory of hay fever and should stimulate to renewed investigations of this interesting malady.

INSURANCE AGAINST MALPRACTICE SUITS.

According to the ruling of the State Insurance Commission of Minnesota, general casualty indemnity companies may write contracts insuring physicians against loss from damage suits for malpractice. This is a new feature of insurance, but it seems to have become prominent elsewhere than in Minnesota. A test case in Massachusetts was the ground of the state official's decision; he is said to have expressed the opinion that such protection is needed not so much by inexperienced and unskilful physicians as by the best and most successful ones as a safeguard against blackmail. In some sections damage suits against physicians and hospitals have become so frequent that the practice of medicine, and more especially surgery, has become so perilous to the pocket

1. Zeitschr. f. Hyg. u. Infektionskr., 1901, xxxviii, 495-499.

that some good operators have thought of giving up practice. The general public has a natural prejudice in favor of an alleged injured person and many unjust verdicts have been given by juries. It has also been considered contrary to public policy to put any limitations to such prosecutions or even to permit insurance against them. It would, however, be still more against public policy to allow honest surgery to be discouraged by facilitating or encouraging blackmail, and this is what the popular prejudice tends to do. A surgical operation or the medical treatment of a case depends for success on too many contingencies beyond the personal control of the practitioner to make their outcome a certainty in any particular case. An unfortunate outcome is, therefore, as it was held in the Massachusetts decision, to be considered an accident in the absence of proof to the contrary, and therefore is legitimately insured against by a casualty insurance company. It is possible that this will be a more frequent recourse of physicians, especially surgeons in some sections, if malpractice suits continue as popular as they have been in the past. The question seems to have been a new one in Minnesota, and it is satisfactory that the supposed legal objections at first raised to this kind of insurance were found invalidated by good legal precedents. Would it be practicable and advisable for the state societies or the AMERICAN MEDICAL ASSOCIATION to take up this work, and such profits as may accrue be kept in the profession, and not be allowed to outside companies?

CAMP-FOLLOWERS OF SCIENCE.

It was prophesied when the *x*-rays were first discovered that they would be exploited by quacks, as there is just that element of mystery and semi-miracle in them that takes in the credulous. We could not well anticipate their real therapeutic value, and we can not say that it has even yet been fully demonstrated. It does appear, however, that they have a certain decided influence on living tissues, and the suggestion is a natural one that this can be applied to a therapeutic end. The success of the Finsen light treatment is also suggestive in this connection. Following out this idea some physicians have experimented with the therapeutic application of these rays and have reported encouraging results in cases of superficial malignant growths, while not claiming any more than logical scientific deduction can allow. There is, however, a class of men, few of them it is satisfactory to say, in the regular medical profession, who are a sort of camp-followers of science, seeking opportunities to pick up something out of new discoveries, or old ones still prominent in the public eye, that they can utilize for personal profit or notoriety. Some of these are comparatively innocent in their methods; they are mere vulgarizers, incompetent ones often, of scientific facts. Others, however, are less unobjectionable, and some recent instances of this will occur to anyone. One or two of the latest have originated in Chicago and have lately taken up space in the daily papers throughout the country, and also, it is reported, in Europe, with alleged claims to cure deep-seated cancers and to destroy all germs by the *x*-ray. It is easy to report cures of anything the existence of which depends upon one's personal diagnosis and statement, if one is unscrupulous enough, and that sort of thing finds many believers. It is another thing, however, to demonstrate them to scientific observers; therefore this kind of discoverer utilizes the daily press which finds his alleged achievements well suited to its sensational needs. What the *x*-rays can do in therapeutics has yet to be shown; the little we know is promising, but no man can truly say that anything more than a limited utility has been proved for them. Simple faith is a beautiful thing in some ways, but in alleged science of the newspapers and especially in the announcement of this sort of medical progress, a healthy skepticism is a better thing. The credulity that formerly exercised itself on ghosts and immaterial things is in this age of discovery lending itself to the fables of pseudo-scientists and often with even worse results.

Medical News.

ARIZONA.

The Territorial Board of Medical Examiners met at Phoenix, November 6, and examined eight candidates.

Dr. Henry J. Otto, of New Orleans, La., has located at Prescott.——Dr. Charles H. Jones, Tempe, who became a member of the Local Board of Health at the time of the smallpox epidemic, has resigned, as the objects for what his services were required have been carried out.

Sanitary Regulations.—Florence has passed an ordinance prescribing regulations for the prevention, limitation and quarantine of contagious and infectious diseases and especially smallpox.——Prescott protects its health by an ordinance prescribing reports of all cases of typhoid fever or tuberculosis; the disinfection of rooms occupied by consumptives; prohibiting expectoration on the ground or sidewalks; regulating the sale of second-hand goods and providing that goods which have been in possession of consumptives be fumigated, and further providing penalties for violation of this ordinance.

A Mecca for Consumptives.—Governor Murphy, in his annual report, insists that the time has come to afford some protection to that part of the population under his jurisdiction in normal conditions of health, and that measures should be taken to separate the consumptives and invalids who visit the territory in the hope of isolation from the residents who are well. He says that Arizona has become a veritable Mecca for consumptives and tuberculous invalids. The dry, salubrious climate of the territory has made it a sanitarium of world-wide reputation, and the southern portion is fast becoming an asylum for the unfortunate people afflicted with pulmonary ills. North and northeast of Phoenix have arisen villages of tents, populated by health seekers who spend their days on horseback and their nights where the unconfined and life-giving air can best reach them. He maintains that, while in the interest of humanity no restraint should be placed on the sick seeking health in Arizona, a law should be adopted that would require segregation and isolation of the afflicted for the protection of the well.

CALIFORNIA.

Communicable Diseases.—Smallpox has appeared near Churntown, where three cases are reported.——Scarlet fever is epidemic at Fruitvale and the public schools have been closed.

Hospital Staff.—The following have been elected on the regular visiting staff of St. Luke's Hospital, San Francisco, for the ensuing year: Drs. Curtis G. Kenyon, Harry M. Sherman, and Charles B. Brigham, surgeons; Drs. Washington Dodge, Clark J. Burnham and George H. Evans, physicians; Drs. Samuel G. Boyd and Charles A. von Hoffmann, gynecologists.

A "strange disease" resembling smallpox is puzzling those physicians of the Centerville district who try to diagnose it as anything except smallpox. Dr. Harry W. Emerson, health officer, declared it to be modified smallpox.

CONNECTICUT.

The State Board of Medical Examiners, at its November session in New Haven, examined 25 applicants for license to practice, three of whom were women.

Litchfield County Hospital.—The new county hospital at Winsted is now practically completed except the furnishing. It will be ready to receive patients by the first of the year. The total cost of the hospital, not including the land, will be about $75,000, of which $30,000 has been provided by the state.

Mortality and Morbidity.—During October 1062 deaths occurred in the state, an annual death-rate of 14 per 1000. Of these 173, or 16.3 per cent., were from infectious diseases. Infectious disease cases were reported as follows during the month: Smallpox, 2; measles, 5: scarlet fever, 208; diphtheria, 176; whooping cough, 44; typhoid fever, 156; and consumption, 7 cases.

DISTRICT OF COLUMBIA.

The hygienic laboratory of the Marine-Hospital Service will soon be erected, as the $36,000 authorized to be expended for this purpose is now available and the contract is about to be let.

Dr. William A. Warfield, Washington, has been made surgeon-in-chief of the Freedmen's Hospital. He has been holding the office temporarily since the resignation of Dr. Austin M. Curtis.

Mortuary Statistics.—For the year ended June 30, there were 6087 deaths in the District, 3430 white and 2657 colored, The annual death-rate was 21.83 per 1000, for whites 17.82 and for colored 30.73. Both rates are in excess of those for the preceding year. The report urges strongly the desirability of medical inspection in the public shools.

GEORGIA.

Smallpox has broken out in a negro settlement ten miles from Athens, where 18 cases are reported.

State Sanatorium Trustees.—Dr. Eugene Foster, Augusta, has been appointed chairman of the Board of Trustees of this institution, and Drs. William S. Elkin, Atlanta, and George D. Case, Baldwin, members of the board.

Mental Science Healers Indicted.—Mrs. Helen William Post, Col. C. C. Post, her husband, and Charles F. Burgman, her son-in-law, have been indicted by the Federal grand jury in Macon, Ga., for using the United States mails for fraudulent purposes in their "mental science absent treatment."

Medical Legislation.—The Macon Medical Society has appointed a committee, Drs. Edward G. Ferguson, Nathaniel T. Carswell and Robert B. Barron, to prepare bills for the legislature, covering the following points: The plan is to have all coroners in Georgia practicing physicians. All proprietary medicines brought into the state must be labeled so that the public can know the ingredients and the proportion of each ingredient. Lunacy juries shall consist of three physicians appointed by the ordinary; one physician must examine the subject on a separate day, and all three shall examine him on the fourth day and make a verdict. No poisonous drug or narcotic, such as morphin, etc., shall be sold without a physician's prescription.

ILLINOIS.

St. Joseph's Hospital, Elgin, will be ready to open the latter part of this month.

New Hospital for Macomb.—The sisters of St. Francis have purchased five acres of land on the outskirts of Macomb, on which to erect a Catholic hospital and sanatorium.

Alton Children Must Be Vaccinated.—The health officer of Alton, acting under authority of the State Board of Health, has issued notice that all children shall be vaccinated without delay.

Brokaw Hospital Completed.—The addition to Brokaw Hospital, Bloomington, has been completed and accepted by the trustees. About a dozen rooms thus far have been furnished by Bloomington citizens and are ready for occupancy.

Marshall Must Go.—Judge Moffatt of Bloomington has dissolved the injunction issued at the instance of Dr. James A. Marshall, house physician at the State Reformatory, Pontiac, to restrain the board of trustees of the institution from ousting him from his position.

Magnetic Healer Found Not Guilty.—A magnetic healer of Lincoln, a graduate of the Chicago School of Psychology and the American School of Magnetic Healing, who was tried for violating the state law regulating the practice of medicine and surgery, was found not guilty by the jury.

Scarlet fever at Washington has closed two rooms of the public school.——The disease is spreading rapidly at Georgetown and the schools will not be re-opened until all danger is past. There are now more than 40 cases with 4 deaths.——Scarlet fever is epidemic at Clinton and the closing of the public schools is being considered.

Smallpox is spreading among the colored people near Rush City. It is said that there are 20 cases in that district.——Smallpox is declared to be present in Alton. The risk of communication of the disease was, as usual, greatly increased because the disease was diagnosed as chicken-pox.——Roseville has four cases communicated by an itinerant evangelist who had no faith in medicine.

Personal.—Dr. George A. Zeller, Peoria, at present serving in the Philippines, has been appointed superintendent of the hospital for the incurable insane at Peoria.——Dr. Festus Burnham, Mason City, has been appointed physician-in-charge of the Illinois Hospital for the Incurable Insane, Peoria.——Dr. William H. Maley, Galesburg, has been appointed alumnus member of the board of trustees of Kave College.——Dr. Harry R. Lemen, Upper Alton, now serving in the Philippines, will resign in May and resume practice.——Drs. Frank C. Becker and Gustave J. Bergener, La Salle, have sold their practice.——Dr. Carl J. Koontz, Galesburg, assistant examiner for the Galesburg division of the Burlington Volunteer Relief department, has been made chief examiner for the St. Louis division, with headquarters at Beardstown.——Dr. Guy G. Dowdall has purchased the practice of Dr. R. C. Fullenwider at Clinton. Dr. Fullenwider has established himself at La Salle, where he will practice.

Chicago.

Examination for Interneships at Dunning.—The competitive examination held under the auspices of the Civil Service Commission for positions on the resident medical staff of the Cook County institutions at Dunning, will be held December 16.

Damage Verdict Set Aside.—In the case of Dr. Edmund R. Moras, who was awarded a verdict of $36,000 against the West Chicago Street Railroad Company, for the loss of a hand, a new trial was granted November 30, on the ground that the verdict was excessive and gave evidence of prejudice against the defendant in the minds of the jurors.

Personal.—Dr. Fenton B. Turck has been made a corresponding member of the French Association of Urology.——Dr. Anthony K. Warner has returned from a three-months' tour of Europe.——Dr. Fred S. Crocker has resigned from the faculty of the Chicago Eye, Ear, Nose and Throat College.——Dr. John M. Moore has been awarded $10,000 damages in his suit against Oliver Sollitt, for slander.

Coroner's Cases.—The report of the coroner for the year ended November 30 showed that 4844 deaths had been investigated; 2479 inquests were held and in 1445 cases the coroner's physician made the investigation. The physician made 910 autopsies. Suicide caused 385 deaths; railway accidents, 290; falls, 206; homicide, 103; drowning, 135; asphyxiation, 60; lightning, 12; horses, 10; hydrophobia, 8; heat, 38; elevator accidents, 27; suffocation, 29; tetanus, 15; poison, 51; machinery accidents, 20; shooting, 11; and scalds, 43.

Strict Hospital Rules.—Under the new rules for the governance of the employes and internes of the Cook County Hospital, employes are prohibited from having any business relations involving patients or the dead with solicitors, undertakers or claim agents. Friends of weak, discharged patients are to be notified when the patients are discharged. Alcoholic patients are to be barred. Detailed records of property possessed by the patients are to be kept by a custodian under bonds. History sheets of each case must be carefully kept.

Chicago Lying-in Hospital and Dispensary.—The annual meeting of the Board of Directors of the Chicago Lying-in Hospital and Dispensary was held December 6. It was decided to broaden the scope of the work, and to this end the Board of Directors was increased to nine members, the Woman's board increased to twenty-seven, and the Medical board arranged so that its members are to be chosen from the three best known of the Chicago medical colleges. The physicians who are to have charge of the medical affairs are as follows: Dr. Joseph B. De Lee, of Northwestern University Medical School; Dr.

Frank B. Earle, of the College of Physicians and Surgeons, and Dr. J. Clarence Webster, of Rush Medical College.

INDIANA.

In Memory of Dr. Todd.—The Marion County Medical Society, at its last meeting, adopted resolutions testifying to the loss sustained by the Society in the death of Dr. Levi L. Todd.

Kile Memorial Opened.—On December 5, the Kile Memorial building, an addition to the Home Hospital, Lafayette, erected with funds contributed by Peter Kile, was dedicated with appropriate ceremonies.

Medical Staffs Announced.—The Indianapolis Board of Health has announced the staffs for the city hospital and the city dispensary. In selecting men for the staffs the effort has been made to treat the Indiana Medical College and the Central Medical College with equal consideration, and other schools outside the city have been given ample representation.

Personal.—Dr. Clarence V. Ward, Indianapolis, has located in Greenfield, and Dr. Clay L. Ward at New Palestine.——Dr. John M. Washburn, Kewanna, has moved to Pulaski.——Dr. Albert J. Buxton, Emporia, has changed his location to New Castle.——Dr. Oscar Heller, New Palestine, has decided to locate at Ridgeville.——Dr. John T. Shields, Seymour, has moved to Vernon.——Dr. Andrew J. Boswell, who recently moved to Elkhart from Fort Wayne, has decided to locate in South Bend.——Dr. John L. Masters, Indianapolis, lecturer on diseases of the eye, ear, nose and throat in the Central College of Physicians and Surgeons, has resigned.

November Mortality.—There were 2402 deaths in the state in November, an annual rate of 11.6 per 1000. In October there were 2614 deaths, a rate of 12.2 per 1000. In November, 1900, there were 2854 deaths, a rate of 13.8 per 1000. From important causes the deaths were: Consumption 293, typhoid fever 156, diphtheria 43, scarlet fever 6, pneumonia 206, cerebrospinal meningitis 13, influenza 10, cancer 88, diarrheal disease 56, puerperal fever 15, violence 106. The cases of smallpox reported were in the following counties: Spencer 54, Randolph 1, Switzerland 10, Jefferson 27, Adams 18, Gibson 13, Pike 1, Dearborn 6, Kosciusko 5, Wabash 5, Marshall 6, Warrick 17, Marion 3, Vanderburg 19, Perry 15. Total 193, two of which died.

IOWA.

Smallpox.—Ida Grove now has 70 cases; Pocahontas, 7 cases; Eldora, 2 cases; Stuart, 5 cases; Blackhawk County, 33 cases; Perry, 3 cases; Council Bluffs, 9 cases; Sioux City, 86 cases, and Des Moines over 100 cases.

Personal.—Dr. Alfred H. Eddy, Cherokee, has located in Oskaloosa.——Dr. Allen L. Bryant, Marshalltown, will move to McCallsburg.——Dr. Louis F. Kelling, New Liberty, has moved to Ely.——Dr. Charles E. Todd, Cherokee, has moved to California.

Children Must Be Vaccinated.—On recommendation of Dr. Nicholas C. Schlitz, city physician of Des Moines, it has been ordained that no child will be allowed to enter public or private schools in that city after Jan. 1, 1902, without evidence or a certificate of successful vaccination.

KANSAS.

Diphtheria has appeared at Whitewater. Several cases have occurred and one patient has died. The public schools have been closed.

Failure to Report Contagious Disease.—On complaint of Dr. Corban E. Judd, city physician of Topeka, a physician of that place has been charged with failure to report a case of scarlet fever within twenty-four hours as provided for by law.

Smallpox.—Secretary Swan of the State Board of Health estimates that the smallpox epidemic last winter cost the state from $75,000 to $100,000.——The State Boards of Health of Kansas and Missouri have agreed to co-operate this winter in the enforcement of quarantine regulations.——Topeka has a case of smallpox.

Personal.—Dr. William H. Fayette, Nickerson, is about to make his home in Oklahoma.——Dr. W. Plily Boal, McArthur, Ohio, has located at Ames.——Dr. Robert S. Magee, Topeka, has been seriously ill with sepsis caused by a cat-bite.——Dr. Horace G. Welsh, Hutchinson, has taken possession of his new hospital.——Dr. William J. Van Eman, Leavenworth, is alarmingly ill with blood poisoning, which has already necessitated the amputation of the right index finger.

KENTUCKY

Measles in epidemic form prevails in Covington, from 800 to 1000 cases of the disease are reported, and several deaths have occurred. The health officer has recommended that the public schools be closed.

Dr. Clark Acquitted.—Dr. W. E. Clark, Sturgis, who was convicted two years ago and sentenced to ten years' imprisonment for causing the death of a young woman by a criminal operation, was given a new trial and was acquitted, November 30.

State Board of Health.—The State Board of Health held a meeting in Louisville, December 21, the object being to consider the smallpox question. The secretary, Dr. J. N. McCormack, was instructed to issue an appeal to every county board of health to erect an eruptive hospital and be prepared to take care of smallpox should it occur. Smallpox is reported in ten counties, Bath, Breathitt, Fleming, Knox, Union, Crittenden, Owen, Washington, Fayette and Bell counties. Dr. McCormack stated that two-thirds of the population of the state outside of the cities had not been vaccinated within the time prescribed by law, and it is the intention of the Board to do all in its power to have every person in the state vaccinated. It is his belief that the situation is extremely critical. The State Board also held a joint meeting with the County Board of Health and the representatives of the city health authorities to make some arrangements in regard to the inspection of cattle and other live stock brought to the new stockyards in Louisville. The matter was referred to a committee which is to appear before the Fiscal court to make definite arrangements for the appointment of an inspector and the fixing of his salary. As the stockyards are located outside the city it is necessary for the Fiscal court to act.

LOUISIANA.

Senses Hospital.—The annual benefit performance of the French opera for the Eye, Ear, Nose and Throat Hospital will be given December 18.

Appointments.—Dr. D. Urban Maes, New Orleans, has been elected resident physician and surgeon of the Touro Infirmary for a term of one year.——Dr. George S. Bel, New Orleans, has been appointed a member of the Charity Hospital board.

To Guard Against Plague.—A conference between the Louisiana State Board of Health and the quarantine authorities of Mobile Bay was held recently in the offices of the Health Board and a new set of regulations to govern vessels coming from plague-stricken ports was adopted.

State Medical Board Election.—The State Board of Medical Examiners met at New Orleans, November 20, and elected Dr. A. Feltus Barrow, St. Francisville, president; Dr. John D. Trahan, Lafayette, vice-president, and Dr. Felix A. Larue, New Orleans, secretary and treasurer. The board will meet to hold examinations for license to practice medicine, May 1 and 2, 1902.

MARYLAND.

New Doctors.—The State Board of Medical Examiners has announced that 23 of those who took the November examination have passed.

Baltimore.

Mortality.—For the week ended November 30 there were 167 deaths, of which 19 were from consumption, 14 from pneumonia, 4 from diphtheria, 3 from typhoid fever and 2 from scarlet fever.

Emergency Boxes.—The Health Department is placing at all police stations tin boxes containing simple medical and surgical supplies, needles, bandages, cotton, etc., and a few staple remedies for use by the health wardens in emergency.

Personal.—Dr. William R. Rogers, assistant resident surgeon at the Maryland University Hospital, has resigned, and will go to Bristol, Tenn., to take charge of his father's business interests. Dr. George W. Hemmeter will succeed him.——Dr. A. G. Watson celebrated the twenty-fifth anniversary of his marriage November 26.

Smallpox.—The first case of smallpox in Baltimore since June 6 was discovered at the City Hospital, November 25, and sent to Quarantine Hospital. All the inmates of the hospital were immediately vaccinated and the building disinfected. The disease is supposed to have been contracted in Philadelphia.

Analysis of City Water.—President Ira Remsen, of the Johns Hopkins University, has made a careful analysis of the city water and fully confirms the statement recently made by

the Health Department, that it is impure and unfit for drinking without boiling. The report is to be made public this week.

The Book and Journal Club held its first meeting of the season November 27. There are about 100 members who pay $5 each yearly, the whole of this sum going to the purchase of new books and journals for the medical library. Dr. William Osler, chairman, entertained the Society over an hour with a description of 100 or more old medical classics purchased by him last summer and presented to the library.

A department of orthopedic surgery has been established at the University of Maryland Hospital under Dr. R. Tunstall Taylor as chief and Drs. Smith, McKin and Riely as assistants. Dr. Taylor will use the children's ward and also will utilize the Hospital for Crippled Children, of which he is chief surgeon. The new department is equipped with the newest apparatus for the most modern treatment of deformities, joint and bone diseases, including a large and powerful *x*-ray machine. Dr. McKim is at present abroad studying.

MASSACHUSETTS.

Smallpox in Boston.—For the week ended November 30, 112 cases of smallpox were reported with 8 deaths, making a total since August of 280 cases with 27 deaths. From November 30 to December 2, 24 new cases were reported.

Franklin County Hospital Appointments.—The medical staff of the hospital met at Greenfield and made the following assignments: December—Dr. Frank H. Zabriskie, attending, and Dr. Howe, alternate; January—Dr. George A. Cooke, Montague, attending, and Dr. Enoch G. Best, alternate; February—Dr. Mary P. Dole, attending, and Dr. Percy G. Davis, Deerfield, alternate; March—Dr. William L. Severance, attending, and Dr. Edwin C. Thorn, Deerfield, alternate; April—Dr. Frank W. Nolan, attending, and Dr. Clara M. Greenough, alternate.

Personal.—Dr. C. B. Adams, who has recently located in Pittsfield, will take charge of the pathologic department of the House of Mercy.——Dr. Paul H. Provandie, Melrose, chairman of the local board of health, has been appointed associate medical examiner for the district, which includes Melrose, Stoneham, Wilmington, Wakefield, Reading and North Reading.——Dr. E. L. Sawyer has purchased the practice of Dr. Charles R. Whitcomb, Roslindale, Boston.——Dr. George W. Dow, Lawrence, has been appointed medical examiner to succeed Dr. Octavius T. Howe.

MICHIGAN.

New Emergency Hospital.—The new emergency hospital to be erected in Detroit for the Detroit Emergency Hospital Association and the Michigan College of Medicine, will have a frontage of 120 feet. It will cost more than $40,000, and will accommodate 110 private patients, in addition to the wards.

Comparative Morbidity.—For the month of November, compared with the preceding month, influenza, pneumonia, pleuritis, diphtheria, smallpox, whooping cough, erysipelas and measles were more prevalent; and diarrhea, typhoid fever, inflammation of bowels, dysentery, cholera morbus and cholera infantum were less prevalent.

Dangerous Communicable Diseases.—Including reports by regular observers and others, cerebrospinal meningitis was reported present during November at 1 place; measles at 27 places; whooping cough at 33 places; smallpox at 92 places; diphtheria at 96 places; typhoid fever at 166 places; scarlet fever at 182 places, and consumption at 198 places.

Smallpox.—At Escanaba, 4 new cases have been reported.——At Sturgeon Bay, there are 16 cases; at Sevastapol, 26 cases, and at Wells several cases.——Muskegon is on the verge of an epidemic; nine cases have been reported.——The country around Alma has several suspicious cases.——At Interlocken a riot was threatened because several patients were removed by the health officer, from a lumber camp to the village.

Personal.—Dr. H. L. Burdeno, Delray, will locate in Dearborn.——Dr. Clark H. Fenstermacher, Marcellus, has gone to Sargent, Neb., where he will resume practice.——Dr. Samuel B. Snyder has removed from Fulton to Kalamazoo.——Dr. Louis Fleckenstein, Port Hope, has purchased the practice of Dr. T. Bennett Scott, Vernon.——Dr. Edward A. Smith, Bay City, has located in Fairgrove.——Dr. S. Edwin Cruse, for the past few years stationed at Quinnesec in charge of the Cundy Mine employes, has resigned and will practice in Iron Mountain.——Dr. J. H. Cole, of the Manistique Hospital, has been appointed chief surgeon of the Manistique and Northwestern Railway, vice Dr. Edward B. Patterson, resigned.——The physicians of Tecumseh met November 26 and passed resolutions expressive of grief and sympathy regarding the death of Dr. Lemon Barnes.——Dr. Norman J. Cramner, Fennville, has moved to Lacota.——Dr. Edward B. Patterson, Manistique, is about to make a tour in Europe.

MINNESOTA.

Diphtheria is epidemic in Forest Prairie and a number of deaths have occurred in the country between Eden Valley and Watkins.——Kimball has had a death from the disease, and the public schools have been closed.——The Health Commissioner of St. Paul has closed Assumption parish school on account of the prevalence of the disease.

Personal.—Drs. Carl J. and Madge Holman have moved from St. Clair to Mankato.——Dr. George J. Hanley resigned as health officer of Cass Lake and will be succeeded by Dr. Ray F. Whetstone, now a resident of Argyle.——Dr. James B. White, Montgomery, has removed to Faribault.——Dr. J. D. Brown, Fergus Falls, has gone to Turtle, Beltrami County, to take charge of a lumbermen's hospital there.——Dr. H. C. Stuhr, McIntosh, has purchased the practice of Dr. Ray F. Whetstone, Argyle.

Smallpox Bulletins.—Dr. Thomas F. Rodwell, Walker, found one case among the Cass Lake Indians, and quarantined the patient.——The disease is prevalent through Norman County, where 76 cases are reported.——Jackson is said to be "honeycombed" with smallpox.——Chaska has 13 cases of smallpox and the public schools have been closed.——Beltrami County has 14 cases, Clay County 14 cases, Carver County 14 cases, Kittson County 12 cases, Marshall County 11 cases, Renville County 12 cases, Minneapolis 6 cases, and St. Paul 1 case. In all 260 cases were reported during the fortnight ended December 5, an increase of 44 over the previous report.

MISSOURI.

Personal.—Dr. J. B. Darcy, Coloma, has located at Bogard.——Dr. Jasper N. Haynes, Eldorado Springs, has moved to Nevada.——Dr. W. Pernell Hall, Nickellton, has located at Lingo.

Hospital Sunday and Saturday Association.—The Hospital Saturday and Sunday Association of St. Louis made its ninth annual collection, November 30 and December 1, and collected $11,712,23 for the sick poor of the city.

Levering Hospital.—Mr. A. R. Levering has agreed to give the city of Hannibal a hospital to cost not less than $25,000 on the following conditions: The building shall be known as "The Levering Hospital"; its conduct shall be absolutely non-sectarian and non-political; and its management shall be vested in a board of control consisting of nine residents of Hannibal.

St. Louis Medical Society Sustained.—The St. Louis Court of Appeals handed down a decison December 3 in the mandamus suit of Dr. W. H. Henderson Mayfield, of the Mayfield Sanitarium, against the St. Louis Medical Society, denying a peremptory writ. The court, in its opinion, stated that the proceedings of the Committee on Ethics of the Society, which found that Dr. Mayfield had violated the rules of the Society and had him expelled, were not malevolent or biased, but were animated by a spirit of fairness and justice; that the relator was bound to the regulations of a member in the Society, and that the Committee on Ethics had the power to try the doctor, and that such bodies may advocate what rules they please, and they will bind the members. Dr. Mayfield was expelled, according to the Court of Appeals, from membership of the St. Louis Medical Society for securing and publishing letters commending his professional work, certificates of his skill and success as a doctor, which was done by issuing pamphlets to the public. Charges that he violated the medical Code of Ethics were preferred against him and the Committee on Ethics was appointed to investigate the case.

NEW YORK.

Measles is epidemic in Dunkirk. In three wards there are nearly 100 cases.

Dr. F. C. Curtis, of the State Board of Health, has gone to Rochester to investigate an outbreak of skin disease which has puzzled the local health authorities of that city.

Personal.—Dr. Fred W. Smith, Richfield Springs, will locate in Utica.——Dr. Strother W. Rice, Carthage, is about to move to St. Regis.——Dr. William H. Jessup, Buffalo, has located in Newark.

Field for Young Physician.—The removal of Dr. Benjamin W. Stearns to Binghamton from Long Eddy, leaves that field

open to some energetic young man to take up a practice of $2000 a year, with no competition in less than eight miles.

State Consumptive Hospital Site Settled.—Governor Odell has ended the long controversy over the site of the State Consumptive Hospital. The institution will be located at Raybrook in the Adirondacks. This decision will give general satisfaction.

Buffalo.

Dr. William J. O'Donnell has been appointed to the staff of St. Mary's Maternity Hospital.

Dr. Lorenzo Burrows, Jr., has been appointed ophthalmic examiner for the New York State School for the Blind at Batavia.

The Smallpox Situation.—Smallpox still continues, but on the whole it is confined to the infected Polish District, although two or three cases have appeared in widely separated localities.

New Health Commissioner.—Mayor-elect Knight has announced the appointment of Dr. Walter D. Greene, the present assistant health commissioner, to succeed Dr. Ernest Wende as health commissioner.

Hospital Overcrowded.—The Buffalo State Hospital for Insane has been much overcrowded, and to relieve this congestion 120 patients, principally New York County patients, will be transferred to the Willard State Hospital and Manhattan State Hospital.

New York City.

Legacy to the Metropolitan Hospital and Dispensary.—By the will of the late Dr. Henri Guilbault, the Metropolitan Hospital and Dispensary of New York, 248 E. 82d Street, receives $3000.

Colored Nurses Graduate.—On December 6, the Colored Hospital graduated a class of trained nurses. In the afternoon they gave a practical demonstration of their proficiency, and in the evening the graduating exercises were held, the feature of which was the address by Dr. T. Gaillard Thomas.

Protection Against Malpractice Suits.—The executive committee of the New York County Medical Association has had under advisement for some time past the problem of how the members of that Association may be best defended against suits for malpractice. The committee announces that it is prepared to submit to the Association, at its meeting on December 16, the outline of a plan. While conceding that this work should be done by the State Association, many of the members in New York County are disappointed with the apparent disinclination of that body to take up this important work.

Personal.—Dr. William H. Guilfoy, for seventeen years connected with the Health Department, has been appointed registrar of records to succeed Dr. Roger S. Tracy, resigned. The appointment was the result of a competitive examination and the salary of the position is $4000 a year.——Dr. Edward Livingstone Tradeau has been appointed a member of the board of trustees of Columbia University.——Dr. Ralph A. Hayt is about to take a six-months' trip through South America.——Dr. John H. Telfair has been made house-surgeon of the Williamburg Hospital, and Dr. Charles Lubrecht ambulance surgeon.

Tenement House Commission.—The physicians of New York City are naturally interested in the work of the Tenement House Commission, and will watch with interest the effect of the first law drafted by that body. It is now announced that Robert W. De Forest, who has in the past been so closely identified with this work, has been selected by Mayor-elect Low to be the first Tenement House Commissioner. He is quoted as believing that "The extreme of the law is the extreme of injustice," from which it is inferred that he will endeavor to administer it conservatively, and yet keep so close to its spirit as to secure better sanitary conditions for the tenement dwellers, who constitute more than one-half of the population of Greater New York. Many physicians believe that in this field a vast deal can be done toward effectively limiting the spread of pulmonary tuberculosis.

OHIO.

Communicable Diseases.—Measles is epidemic in Springfield and Cincinnati; scarlet fever in Columbus; diphtheria in Cambridge and smallpox in Magnetic Springs.

Akron City Hospital Staff.—The officers and medical staff of the City Hospital were re-elected November 26. In addition, Dr. H. I. Cozad was elected pathologist; Dr. W. S. Chase, bacteriologist, and Drs. J. A. Hulse and G. W. Stauffer, anesthetists.

Personal.—Dr. Stephen A. Cunningham, Marietta, is dangerously ill from a septic wound of the hand.——Dr. Claude N. Chrisman, Dayton, has gone to Missouri, where he hopes to regain his health.——Drs. L. J. Spickard, Columbus, and R. G. Bazelle, Rock Camp, have joined forces and will practice in Ironton.——Dr. Thomas W. Walker, Steubenville, is critically ill.——Dr. Albert Hathaway, Nettle Lake, has located at Edon.——Dr. Guy McFall, Sandusky, has settled in active practice at Detroit.——Dr. Kennon Dunham, Cincinnati, has left for a year's study abroad. The greater part of his stay will be in London.

PENNSYLVANIA.

Donation to German Hospital.—On "donation day" at the German Hospital, Philadelphia, the friends of the institution gave more than $10,000 in cash and supplies.

Personal.—Dr. Harry W. Dechert, Tamaqua, has been appointed deputy coroner for the Orwigsburg district.——Dr. Francis B. Davison, who has practiced for many years at Fleetville, has moved to West Pittston.

Smallpox in Philadelphia.—The epidemic of smallpox in the city has assumed serious proportions. During the last week, 113 new cases were reported. More than 1000 homes are under quarantine, the municipal hospital is overcrowded and no other hospital will receive smallpox cases. It is said that in the last three months 800,000 individuals have been vaccinated. The mortality for the week from the disease was 14.

Tetanus and Vaccination.—The State Board of Health and Vital Statistics of Pennsylvania has transmitted the following resolutions adopted at a regular meeting held at Harrisburg, November 21: "Resolved, That in view of the very natural public apprehension in regard to the possibility of tetanus following vaccination, as illustrated by recent cases of this accident in a neighboring state, this Board desires to state its conviction founded upon a careful study of the history of vaccination and of the cases referred to, that it has yet to be demonstrated that vaccine virus ever contains or becomes contaminated with the germ of tetanus. When such occurrences as those referred to take place, it is because, owing to carelessness, usually on the part of the person vaccinated, the germs of tetanus have gained access to the wound on the arm as they may to any other wound, abrasion or scratch upon the surface. Resolved, That there is no reason for dreading, or abstaining from vaccination, because of these recent cases. This is sufficiently demonstrated by the fact that more than half a million persons have been vaccinated in and around the City of Philadelphia within the past few months without the occurrence of a single case of tetanus. Resolved, That, inasmuch as new cases of smallpox are being reported to the Board daily from all parts of the state, the present would be a most unfortunate time to interrupt the general vaccination which is now in progress. Resolved, That this Board condemns in the strongest possible terms, the use of any material or medicament administered by the mouth as a substitute for vaccination, and that any physician furnishing a certificate of successful vaccination based upon the administration of any such substance or remedy, lays himself open to prosecution for violation of a state law. Resolved, That this Board reaffirms its previous declaration of confidence in the value of vaccination as a preventive or modifier of the severity of smallpox, and its belief that the possibilities of serious results following its performance must be looked upon as infinitesimal in comparison with the inestimable advantages derived from the same.

CANADA.

Appointment.—Dr. R. Boulet of the Ophthalmic Institute, Montreal, has been appointed director of the dispensary of the eye and ear department of the Hotel Dieu Hospital.

Samaritan Hospital, Montreal.—At the last regular monthly meeting of the Board, the surgeon-in-chief, Dr. Lapthorn Smith, announced that the work at this institution during the past summer was the heaviest since the hospital was opened by Lady Aberdeen eight years ago. It is expected that every bed will be occupied from the present time until spring; and as evidencing the purely charity work of this hospital, there is only one private patient in the wards at the present time.

Quebec Licenses to Practice.—The College of Physicians and Surgeons of the province of Quebec has decided to issue licenses to all physicians who present university diplomas,

without further examination. This action of the College applies only to those who come under the operation of the statute of the Quebec Legislature, known as the Roy law, which was adopted two years ago. The courts have rendered several decisions recently adversely to the College, holding that the College was bound to give licenses to those who came under the operation of this law.

Compulsory Vaccination at McGill.—Owing to the extensive outbreak of smallpox in the province of Quebec, compulsory vaccination is ordered at McGill University, and the authorities have decided to enforce the requirements of the Public Health Act in this respect. Vaccination is going on in the Medical Building, daily, and it will take a few days to complete the entire number as there are over 1200 students in the various departments at McGill.

Charitable Bequests.—By the will of the late Mr. W. E. H. Massey of Toronto, 1000 shares of stock in the Massey-Harris Manufacturing Company, valued at $100 per share, has been willed to various charitable and religious objects. Victoria University, Toronto, gets five-twentieths of this amount. One-twentieth is to be handed over to the Sick Children's Hospital, Toronto, to endow and maintain a cot in that institution. One-twentieth is left to the Trustees of Boston University, Boston, Mass., and one-twentieth to other charities in Toronto.

Death While Administering Chloroform.—A man aged 53 years recently died at the Western Hospital, Toronto, while undergoing an operation; as the house surgeon who was administering the anesthetic had not fulfilled all the requirements of the Ontario Medical Law entitling him to practice his profession, the death caused some little comment. A coroner's jury investigated, when it was found that no blame was attached to the young doctor in question, although the cause of death was set down to chloroform poisoning through anesthesia. The jury strongly recommended that in hospitals in the city where operations were performed, a specially appointed and competent anesthetist should have charge of this work.

Toronto Clinical Society.—This society held its regular meetings on November 6 and December 4. At the former meeting, Drs. George A. Bingham and J. T. Fotheringham reported a case of thyroidectomy in a female aged 30 years. This condition of enlarged gland, etc., had continued for four or five years, during which time she decreased in weight from 167 to 120 pounds. Dr. Bingham performed the operation through an incision extending from the left mastoid process to the sternum, closing up the cavity which remained by quilting with several rows of catgut sutures. Both gentlemen were very much impressed with the use of the ice bag to the precordia for subsequent tachycardia. Dr. J. Algernon Temple reported a case of Paget's disease of the nipple and showed the fresh pathologic specimen. The disease occurred in an unmarried woman aged 45 years, and a year prior to the operation no growth could be found in the breast. Dr. Temple removed the entire breast with all the fatty tissue clean down as far as the pectoral muscle. In the above two cases the patients made good recoveries. At the December meeting an interesting case of blastomycosis in a man of 50 years, an engineer, was shown by Dr. Graham Chambers. The lesions were situated on the nose, upper lip, cheeks and backs of the hands and fingers. Although Dr. Chambers had not as yet demonstrated the fungus under the microscope, he believed he had made the correct diagnosis. The lesions are undergoing marked improvement under large doses of iodid of potash. Dr. A. J. Harrington reported a case of mushroom poisoning from a very small raw piece of the fungus, with recovery. His treatment practically amounted to two hypodermic injections of atropin. The president, Dr. J. F. W. Ross, showed two specimens of ectopic gestation occurring in a woman at the same time. One was advanced to three and one-half months, while the other was about six weeks. The patient made a good recovery from the operation, although she nearly collapsed while on the table. Dr. Rose stated that he had had four cases of ectopic gestation following on a previous operation for the same condition.

FOREIGN.

Plague at Rio de Janeiro.——Four new cases of the plague and one death were reported at Rio de Janeiro, on December 3.

Prof. W. His, Jr., has resigned his chair at Leipsic since his appointment to be medical superintendent of the city hospital at Dresden.

Deaths Abroad.—Dr. K. von Liebermeister, professor of internal medicine at Tübingen, Niemeyer's pupil and successor.——Dr. A. Villard, professor of clinical medicine at Marseilles.——Dr. G. Chiarleoni, professor of obstetrics at Palermo. ——Dr. A. Maseras, professor of medical pathology at Manila.

Insurance Company's Consumptives' Home.—The German insurance company "Berlin," has erected at Lichtenberg a home for consumptive policy-holders. The expense of total maintenance is much greater than the payment of the individual indemnities, and the institution is thus exclusively for the benefit of the inmates.

LONDON LETTER.

Plague in Glasgow.

All fear of immediate extension of the outbreak of plague has now practically ceased. There have been no new cases during the last three weeks, and the hotel where the original patients were employed has been thoroughly disinfected and is to be reopened. The Local Government Board of Scotland has intimated approval of the order of the local authority making plague a notifiable disease within the city until Dec. 31, 1902. Dr. A. K. Chalmers, the medical officer of health, has issued a circular dealing with the relationship of ships entering and leaving the port, and with the conditions which they must adopt in order to avoid prolonged detention in quarantine. He advises that continuous efforts should be made to destroy rats on board ships, and advises for this purpose sulphur fumigation when the holds are empty.

Pestis Minor in London.

A case of "pestis minor" has occurred. A man aged 24, a lighterman on the Thames engaged in unloading merchandise from the Baltic, applied to the West London Hospital with lumps in his groin. Three weeks previously he fell and hurt the lower ribs on the right side. To this he ascribed the subsequent swelling of the glands. By November 4 he had to cease work. There were severe headache, a temperature of 101 F., furred tongue, injected conjunctivæ, enlarged spleen, swollen inguinal glands and some enlargement of the cervical and axillary glands. In either groin two or three glands could be felt, one of which was as large as a walnut. The overlying skin was not red, but exquisitely tender. The bacteriologic examination made by Dr. Klein negatived true plague. The disease was probably pestis minor—a specific form of glandular enlargement which occurs when plague threatens or is actually prevalent. In pestis minor the plague bacillus is only occasionally found, and then in an involuted form. Rats have been destroyed in enormous numbers; from September 23 to October 27 14,610 were killed, making a total up to that date of 75,424.

Plague in India—Commission's Report.

A valuable report on the outbreaks of plague in India in recent years has been issued. In November, 1898, a commission was appointed by the Indian Government to investigate, 1, the origin of the outbreaks; 2, manner in which the disease is communicated; 3, effects of curative serum; 4, effects of preventive inoculation. The members of the Commission were: Dr. Fraser, professor of materia medica in the University of Edinburgh; Dr. Wright, professor of pathology in the Army Medical School, Netley; Mr. A. Cumine, senior collector in the Bombay Presidency, and Dr. M. A. Puffer, president of the Sanitary, Maritime and Quarantine Council of Egypt. The report is very voluminous and exhaustive, covering over 400 pages of a bulky "blue-book," apart from appendices. The most important part is that dealing with Haffkine's anti-plague inoculation. The following are the conclusions: 1. Inoculation diminishes the incidence of plague attacks, but the protection is not absolute. Plague has attacked persons who have been inoculated as often as four times in the course of the two years previous to the attacks, and as many as 8 per cent. of the inoculated population may suffer from plague. 2. Inoculation diminishes the death-rate of those attacked. Here again the Commission has been unable to state the effect numerically. 3. Inoculation does not appear to confer any great protection within the first few days. 4. The protection conferred by inoculation certainly lasts a considerable number of weeks, possibly a number of months. The Commission recommends accurate standardization of the vaccine for the attainment of the best results, stringent precautions against contamination, and encouragement of inoculation whenever possible. With reference to the serum therapeutics, especially the serums of Yersin and Lustig, they say that though the success is in no way comparable to that obtained in the serum treatment of diphtheria yet the method, as in other infectious diseases, is the only one which holds out a prospect of ultimate success. As to the measures for the suppression of plague in

India the Commissioners say that while all have not been beneficial every possible experiment has been tried and every possible effort made to restrict and eradicate the disease. They point out that increased communications now render the spontaneous disappearance of plague less probable than formerly.

Smallpox in London.

The outbreak of smallpox is still increasing. The number of patients under treatment which had been 172, 180, 284 and 297 in the preceding weeks, has risen to 368 according to the last weekly return. The number of cases is still increasing, for there are 402 in hospital. In connection with the present epidemic the history of previous ones is of interest. The Registrar-General's returns, which commenced in 1838, show that the disease appeared in London in epidemic forms at intervals sometimes as short as 2 years, sometimes exceeding 5 years, until the great epidemic of 1871-72, when no fewer than 10,671 deaths occurred. The next epidemic occurred in 1876-78 with 4704 deaths, one in 1881 with 2367 deaths, one in 1884-85 with 2665 deaths. Then a great change was made in the method of isolating cases. Up to this time the hospitals were situated in London, but in 1884 hospital ships were established 18 miles down the Thames River. Only milder cases were sent to the ships. Subsequently all cases were sent as no ill-results occurred from the practice even in the most acute. In the three years, 1886-88, only 42 deaths from smallpox of London residents occurred; in 1889 not one; in 1890 and 1891, 11.

Royal College of Surgeons: Annual Meeting of Fellows and Members.

The annual meeting of the Fellows and Members was held at the College. The president presented the annual report. The usual annual resolution which has been passed for the last 17 years that the members should have a voice in the government of the College was passed. The College is governed by a Council consisting entirely of Fellows who are elected only by Fellows. The members, who number 16,000, have no voice in the matter whatever. However, as the Fellows are much the most highly educated section—the consultants of the surgical profession—this oligarchy of ability has its advantages. With true English conservatism the resolution passed at the annual meeting, the only opportunity that the members ever have of expressing any opinion in the government of the College, is always ignored by the Council.

London Fogs.

The reputation of the terrible London "pea-soup fogs" which turn day into night, is well known. They result from the suspension in the atmosphere of minute particles of carbon the result of the incomplete combustion of coal. At a recent meeting of the "Coal Smoke Abatement Society," Sir William Broadbent moved a resolution that "the pollution of the air by coal smoke is injurious to the public health and vitality, destructive of works of art and vegetation, and demoralizing to the inhabitants of a great city." Comprehensive as was this indictment it was not exhaustive. Every fog is a death warrant to a number of sufferers from bronchitis and heart disease. No one can live in London to a certain age without having his lungs speckled with carbon. The suburb of Kew, where are the celebrated botanical gardens, was once comparatively pure. Now, owing to the metropolitan extension, it is invaded by fog. During the prolonged fog of 1891 leaves fell in the palm houses in Kew Gardens and were swept away by the bushel. This was the result of the withdrawal of light. In addition, there was a deposit on the glass houses which resembled brown paint. It was calculated that this deposit was equivalent to the distribution of 6 tons of solid matter per square mile in the course of a week. This Society makes observations of offending shafts in which the production of smoke exceeds the legal limit and compels the owners to abate the nuisance. Since its foundation in March, 1899, it has carried out 2750 observations of offending shafts, made 1690 complaints and secured the imposition of fines amounting to $3500.

Correspondence.

Appendicectomy—Surgical History.

PHILADELPHIA, Dec. 9, 1901.

To the Editor:—In the interesting article appearing in last week's JOURNAL, contributed by Dr. B. Merrill Ricketts, of Cincinnati, upon "Appendicectomy—Surgical History," to which is appended a bibliography of the subject, from 1758 to 1888, there occurs a notable omission, that has doubtless not escaped the observation of some of your readers, and for supplying which I feel assured that Dr. Ricketts will be the first to thank me in the interest of accuracy and in justice to American surgery. By referring to THE JOURNAL I find that in Vol. x, on page 733, Dr. Thomas G. Morton of Philadelphia published an article entitled "The Diagnosis of Peri-Cecal Abscess and Its Radical Treatment by Removal of the Appendix Vermiformis." In this communication, Dr. Morton refers to a case, which had been diagnosed by two physicians as one of appendicitis, in which view Dr. Morton concurred and promptly operated by celiotomy and extirpation of the diseased appendix. This operation was performed on April 23, 1887, and therefore antedates the cases both of Sands (Dec. 30, 1887) and McBurney (May 23, 1888). The case operated upon by Morton had been reported by the undersigned, to the College of Physicians of Philadelphia, at its meeting one June 1, 1887 (Transactions of the College of Physicians, 3 Series, Vol. ix, page 183). The statement appearing in Dr. Ricketts' paper (p. 1534) that McBurney's patient (May 23, 1888) was "the first case in which an operator had deliberately planned for and did remove a diseased appendix" would be likely to convey a false impression, if attention were not at the same time directed to this case which had been correctly diagnosed and the operation of removal of the appendix deliberately planned and the plan successfully carried out by Morton more than a year before the date assigned by Ricketts, as that of the first operation of its kind. It perhaps should be stated that Dr. Morton was led to decide upon extirpation of the diseased appendix by his experience in a similar case a few months previously. On Feb. 21, 1887, he had performed a celiotomy for Dr. E. R. Stone, of this city, upon a woman suffering with peri-cecal abscess, in which the appendix was found to be extensively diseased. In this case also he ligatured the appendix at its base and removed the organ; but in this patient the diagnosis of appendicitis had not been positively made and removal of the appendix decided upon previous to the section. This case has also been reported (Transactions of the College of Physicians, Vol. ix, p. 189). The subject of the other operation was a young man who made a perfect recovery and is now engaged in active business life. References to this now celebrated case will also be found in THE JOURNAL for July 25, 1891 ("On Appendicitis with Peri-Cecal Inflammation" by Dr. Thomas G. Morton) and also in the Transactions of the Philadelphia County Medical Society for Dec. 14, 1887 ("Treatment of Peri-Cecal Inflammation" by Thomas G. Morton, M.D.)

Very respectfully yours, FRANK WOODBURY.

The Army Canteen.

HARTFORD, CONN, Dec. 6, 1901.

To the Editor:—The American Public Health Association is composed of many very practical men, and it is reasonable to suppose that they knew what they endorsed by vote at a recent session. The following resolution was offered and considered in a committee, then unanimously passed in the general session of the Association:

"Resolved, That this body deplores any action in curtailing the operation of army canteens or post exchanges and in the interest of general and military sanitation and temperance recommend their establishment *as formerly existing in the United States.*"

The spirit interests have circulated this resolution very widely as evidence that the canteens, with beer and spirits, are needed to keep the army temperate and sober. The "anti-canteeners" are using the same resolution to demonstrate that the public health doctors want no change, but recommend the establishment of the canteen "as formerly existing in the United States," which was originally without beer or intoxicants. The zeal of the authors of this resolution is more pronounced than their accuracy of statement; as a result the Association is placed on the fence, to come down on the side most convenient.

Very truly yours,

T. D. CROTHERS, M.D.

Married.

JOHN MARDER M.D., Venice, Ill., to Miss Ella Sommer, at St. Louis, November 23.

AUGUST W. SEIDLER, M.D., to Miss Mary C. Shields, both of Baltimore, November 24.

SHERIDAN A. LOCKWOOD, M.D., to Myrtle E. Spencer, M.D., both of Portland, Oregon.

J. PAGE MASSIE, M.D., Richmond, Va., to Miss Cynthia Mundy, daughter of Dr. John C. Mundy, of Allen's Creek, Va., November 27.

Deaths and Obituaries.

Sir William MacCormac.—In our last issue a brief announcement was made of the death of Sir William MacCormac, which occurred suddenly at Bath, England, from heart disease. As one of the greatest British surgeons of the day, his career calls for a rather more extended notice. William MacCormac was born Jan. 17, 1836, at Belfast, Ireland. The son of a physician, he followed his father's profession, and received a general and professional education at Belfast, Dublin and Paris. Though he held honorable professional positions before, his first general prominence was due to his observations during the Franco-German war of 1870, which he published in a work that has been translated into the German, French, Spanish, Italian, Russian and Japanese languages and made him the great authority at the time on military surgery. His subsequent service in the Turko-Servian war enlarged his experience in this line, and his recent connection with the surgical history of the Boer war is so recent as to be known to all in the medical profession. His standing with his confrères can be judged by the fact that he was several times elected president of the Royal College of Surgeons, and the honors he received from his own and other governments are almost too numerous to mention. His connection with the International

SIR WILLIAM MACCORMAC, F.R.C.S.I., F.R.C.S. ENG., ETC.

Medical Congress of 1881, to which he acted as Hon. Secretary-General, and to the success of which it is said he contributed more than any other man, brought him the honor of knighthood; he was made a baronet and surgeon-in-ordinary to the Prince of Wales in 1897. Besides his European honors, his work as a surgeon was recognized in this country by his election to the honorary fellowship in the American Surgical Association. At the time of his death he was consulting surgeon and emeritus lecturer in clinical surgery at St. Thomas' Hospital, the institution with which he was an active medical teacher for twenty years; his services and name were in demand in other hospitals and in various official positions. His death at the comparatively early age of 65 has deprived Great Britain of one of its most brilliant authorities in surgery. His best known works are "Notes and Recollections of an Ambulance Surgeon," 1871; "Antiseptic Surgery, Its Principles and Practice," 1880; and "Surgical Operations," 1885. His addresses, contributions to composite works, and separate articles would make an extensive list.

Josiah Abbott, M.D. College of Physicians and Surgeons of the Western District of New York, Fairfield, 1840, a veteran of the Civil war, in which he served as assistant surgeon of the 13th Heavy Artillery and as surgeon of the 119th U. S. Volunteer Infantry, who had practiced for half a century in Rindge and Winchendon, Mass., died at his home in the latter place, November 27, from paralysis, after an illness of only a few hours, aged 90.

David S. Perkins, M.D. Jefferson Medical College, Philadelphia, 1883, a member of the American Medical Association, formerly of Cleveland, Ohio, but for the last three years a resident of New Mexico, and medical director of the Montezuma Hotel, Las Vegas Hot Springs, died at El Paso, Texas, November 30, after an operation for tuberculosis of the liver.

Moses Marshall, M.D Ensworth Hospital Medical College, St. Joseph, Mo., 1885, a prominent physician of Easton, Mo., died at his home in that place, December 2, from blood poisoning from a wound on the hand by the fin of a catfish, after an illness of ten days, aged 48.

J. C. Munday, M.D. Tulane University, New Orleans, La., 1872, who had practiced in Lake Charles, La., until last winter, when, on account of ill-health, he removed to San Antonio, Texas, died at his home in that city from tuberculosis, November 24, aged 55.

James S. Bibby, M.D. Bellevue Hospital Medical College, New York, 1875, a practitioner of Paterson, N. J., for twenty-five years, died at his home in that city, November 28, from pneumonia, aged 58. He was a member of the Passaic District Medical Society.

J. R. Barkley, M.D. Memphis (Tenn.) Hospital Medical College, 1892, a resident of Woodburn, Miss., who was kicked in the knee by a horse and brought to the King's Daughters' Hospital, Greenville, Miss., for treatment, died there, November 30, aged 35.

John W. Brock, M.D. Starling Medical College, Columbus, Ohio, a member of the Noble County Board of Pension Examiners and a prominent physician of Caldwell, Ohio, died at his home in that place, December 3, from acute brain disease, aged 51.

David McDill, M.D. Rush Medical College, Chicago, 1887, Burlington, Iowa, died at the United States Military Prison, Fort Leavenworth, Kansas, where he was appointed surgeon a year ago, from apoplexy, December 4, aged 41.

Patrick J. McKenna, M.D. Tulane University, New Orleans, La., 1888, died as the result of fracture of the skull received by a fall from a railway train, at the Keogh-McKenna Hospital, Salt Lake City, Utah, November 29.

John C. Hartt, M.D. Long Island College Hospital, Brooklyn, N. Y., 1892, died at Kings County Hospital, Brooklyn, November 24, from skull fracture received in a fall from his horse six days previously, aged 40.

Charles B. Osborne, M.D. University of Buffalo, N. Y., 1890, coroner of Seneca County, N. Y., died at his home in South Waterloo, N. Y., December 2, from acute nephritis, after an illness of one week, aged 54.

Charles S. Essig, M.D. Jefferson Medical College, Philadelphia, dean of the dental department of the University of Pennsylvania, died at his home in Wallingford, Pa., from pneumonia, December 2.

Magruder Muncaster, M.D. University of Maryland, Baltimore, 1883, formerly of Washington, D. C., died at Rockville, Montgomery County, Md., November 28, from Bright's disease, aged 42.

Johnson G. McCullough, M.D., the oldest practicing physician in Belmont County, Ohio, died at his home in Bellaire, November 15, from paralysis, after an illness of three weeks, ager 75.

Adolph Wermuth, M.D. Fort Wayne (Ind.) College of Medicine, 1898, died at the residence of his parents in Fort Wayne, Ind., November 27, after an illness of fourteen days, aged 23.

Charles W. Ballard, M.D. Washington University School of Medicine, Baltimore, 1847, died at his home in Braidentown, Fla., November 27, from heart disease, after a short illness, aged 75.

Daniel Vortner Sevier, M.D. University of Louisville, Ky., 1854, who spent an active life in the practice of medicine in Franklin County, Ala., died at his home in Russellville, recently, aged 78.

I. Newton Evans, M.D. Jefferson Medical College, Philadelphia, a member of Congress for three terms, died suddenly at his home in Hatboro, Pa., November 3, from heart disease, aged 74.

Levi Hasseltine, M.D. Castleton (Vt.) Medical College, a practitioner of Bristol, Vt., for more than thirty years, died at the house of his son in Pittsford, Vt., November 26, aged 82.

James E. Gibbons, M.D. Washington University School of Medicine, Baltimore, Md., 1868, a physician of Baltimore, died suddenly from heart disease, December 2, aged 58.

T. Hampton Cook, M.D. Medical College of Ohio, Cincinnati, 1880, died at his home in Scio, Ohio, November 25, from cancer, after an illness of two years, aged 50.

John A. Elliott, M.D. Memphis (Tenn.) Hospital Medical College, 1886, died at his home near Bonicord, Tenn., November 26, from consumption.

George R. Edwards, M.D. University of Wooster, Cleveland, Ohio, 1883, died from Bright's disease, at his home in Los Angeles, November 28.

Edwin Davis, M.D., ensign and assistant surgeon U. S. Navy, a native of Louisville, Ky., died at Las Vegas, N. M., November 15.

C. L. Broaddus, M.D. University of Nashville, Tenn., 1899, died suddenly from heart disease at Wallonia, Ky., December 1, aged 40.

Henry C. Houghton, M.D. New York University, 1867, died suddenly at his home in New York City, December 1, aged 64.

O. C. Brittain, M.D. Atlanta (Ga.) Medical College, 1886, died at his home in Franklin, Ga., November 23, aged 64.

Carl Schenck, M.D., died from consumption at his home in Franklin, Ohio, November 27, aged 31.

Books Received.

THE SURGICAL AND MEDICAL HISTORY OF THE NAVAL WAR BETWEEN JAPAN AND CHINA, During 1894-1895. Translated from the Original Japanese Report, Under the Direction of Baron Saneyoshi, F.R.C.S. Eng., Director-General of Medical Department of Imperial Japanese Navy, by S. Suzuki, M.R.C.S. Eng., L.R.C.P. Lond., Deputy Inspector-General of Hospitals and Fleets, Imperial Japanese Army. Cloth. Pp. 544. Tokio: Printed by Tokio Printing Co., Ltd. 1901.

If there was ever any question as to the standing of Japan as a civilized nation the edition of a work like this would help to settle it in the affirmative. This handsome volume contains an account of the medical side of the naval operations during the Japanese-Chinese war and is the first elaborate contribution to the medical history of extensive naval operations in war under modern conditions. In fact, the battle of Yaru, as the Japanese spell it, though we have been used to call it Yalu, is the most extensive conflict of which medical records are available in which ironclads and modern weapons were employed. Our Spanish-American war gives us very little medical history of this kind, as the casualties on the American ships were so few. If we could get the Spanish side of it this would probably be different, but circumstances will probably forever forbid that. The volume contains an elaborate history of all the cases discussed and classified, including shell wounds, splinter wounds, powder burns, shock, steam burns, bullets, collision injuries, etc. The volume is instructively illustrated and translated by Dr. Suzuki into generally excellent English; only here and there a slip shows its foreign origin. It is in all respects a valuable contribution to the

medical history of naval warfare. It also covers the medical conditions of the Japanese fleet during the Chinese-Japanese war, discussing also such diseases as kakkè or beri-beri, which the Japanese authorities do not regard as infectious, but rather as a dietetic ailment. As the Japanese medical men have probably had a larger experience with it than any others, we must respectfully regard their opinion, even though it may not be our own. It is not stated in the work that it is a government publication, but we take it that this is the case, and if so, it is a credit to the government which sends it out.

Dictionary of Philosophy and Psychology, Including Many of the Principal Conceptions of Ethics, Logic, Anesthetics, Philosophy of Religion, Mental Pathology, Anthropology, Biology, Neurology, Physiology, Economics, Political and Social Philosophy, Philology, Physical Science, and Education, and Giving a Terminology in English, French, German and Italian. Edited by James Mark Baldwin, Ph.D. (Princeton), Hon. D.Sc. (Oxon.), Hon. LL.D. (Glasgow). Stuart Professor in Princeton University. With the Cooperation and Assistance of an International Board of Consulting Editors. In Three Volumes, with Illustrations and Extensive Bibliographies. Vol. I. Cloth. Pp. 644. Price, $5.00. New York: The Macmillan Co. 1901.

This is the first volume of a work that, while not professedly medical, is one that any physician who reads and thinks can profitably utilize. The relation of psychology to medicine ought to be apparent enough to prove this statement without argument. This work, however, covers not only the subjects usually included in a dictionary of philosophy with psychology as an included branch, but those of biology, neurology and psychiatry which have in these later days come to be also in the cognizance of the student of human mentality. It is an encyclopedia dictionary not only of philosophy but also to a great extent of physiology and psychologic pathology. Its usefulness to the physician therefore is obvious; it can be of aid to him in his professional work as well as in his general culture. The consulting editorial staff includes names as well known in medicine as Exner, Ziehan and Morselli, and among the contributors those of Adolph Meyer, Hodge, Minot and others; they ought to be assurance that our science is adequately represented. There is no work like it in our language, no other that attempts to so fully cover the terminology of biologic, physiologic, mental and moral science as this does, or that more satisfactorily succeeds in its aim. The medical subjects are generally handled in a way that will prevent their losing their utility by soon falling behind the times and the work will long be a standard work of reference. The bibliographic references appended to each subject treated at length, materially add to its value. There is hardly any other work not strictly medical, that can be more sincerely recommended as an addition to the physician's library.

A Text-Book on Diseases of the Ear, Nose and Throat. By Charles H. Burnett, M.D., E. Fletcher Ingals, M.D., and James E. Newcomb, M.D. With Numerous Illustrations. Cloth. Pp. 734. Price, $5.00. Philadelphia and London: J. B. Lippincott Co. 1901.

This work on co-related branches has been written by leading specialists and teachers in their respective departments of otology, rhinology and laryngology. Each of the triad of subjects is introduced by a concise, yet thorough, description of the anatomy and physiology of the parts. It seems almost needless to say that the treatment is up to date in every respect. The mechanical make-up of the book, with regard both to material and workmanship, is beyond criticism. By means of large, well-filled pages, with a clean and clear type, the publisher has been enabled to bring the three allied subjects, thoroughly considered, within the limits of a conveniently sized treatise. It is certainly one of the best text-books on these branches before the profession, and as such we unhesitatingly recommend it.

Irregularities of the Teeth and Their Treatment. By Eugene S. Talbot, M.D., D.D.S., Professor of Dental and Oral Surgery, Northwestern University, Woman's Medical School. Fourth Edition. With 580 Illustrations. Cloth. Pp. 546. Price, $5.00. Philadelphia: F. A. Davis Co. 1901.

This fourth edition of Dr. Talbot's work, which is slightly altered in its title, has been thoroughly revised and in some portions at least is almost a new work. The last edition was received by the scientific world with much favor and it seems likely that this present edition will be even more satisfactory. The principal changes have been made in the first portion where he discusses the general principles of degeneracy and its causes. It is here almost an entirely new work; the latter part also has been revised, contains a much larger number of illustrations and statistical tables, and a great deal of new matter scattered throughout the text. There is no dental work that we know of which is more scientific than the present one, though in its form and general composition it is less difficult and technical than many pretentious works. The general make-up of the book is greatly improved over the previous volume.

Text-Book of Nervous Diseases, Being a Compendium for the Use of Students and Practitioners of Medicine. By Charles L. Dana, A.M., M.D., Professor of Nervous Diseases in Cornell University Medical College. Fifth Edition. With 244 Illustrations. Cloth. Pp. 633. Price, $3.50 net. New York: William Wood & Co. 1901.

This work, which has been much enlarged during the successive editions through which it has passed since its first appearance, has been revised and somewhat added to in the present one. The chapter on myelitis has been rewritten; a chapter on general paresis has been added, including this, as is proper, among the nervous diseases falling wholly as much to the specialty of neurology as to psychiatry. The author's experience with this disorder is of interest in that he shows a large proportion of Hebrews among his private cases, in this matter agreeing with a recent English observer who has called attention to this prevalence. The chapter on myelitis has been completely rewritten and though the author does not speak of the other changes that have been made, they seem to be such as add to the value of the work. The book is one that will undoubtedly continue to meet with the general favor that it has thus far received by the profession.

Diseases of the Respiratory Tract—The Nose, Pharynx and Larynx. By P. Watson Williams, M.D. Lond., Physician in Charge of the Throat Department at the Bristol Royal Infirmary: Physician to the Bristol Institute for the Deaf and Dumb. Fourth Edition. Illustrated. New York, London and Bombay: Longmans, Green & Co. 1901.

The rapid passage of this work through three previous editions bespeaks its popularity. This last edition contains over 400 pages of text besides an appendix of useful formulæ. It has nearly 250 illustrations, 37 of which are exceptionally fine plates, some of them colored, the others adapted to the stereoscope, which instrument the author has had slipped into a pocket in the cover of each volume. Its use, however, adds but little of practical value to the cuts. A feature of the fourth edition is the amplification of the sections on diphtheria and the diseases of the nasal accessory sinuses. If any special adverse criticism is to be offered it would be that many of the sections on treatment, as for instance, that on hypertrophic rhinitis deal with the subject too much in outline, without sufficient attention to details of method to be of service to the general practitioner and beginner on the one hand, or on the other, to the laryngologist already versed in technique of one or more methods.

Miscellany.

Gelatin Treatment of Aneurysm.—Brilliant success is reported from the subcutaneous injection of 175 to 220 gm. of a 2 per cent. solution of gelatin, repeated ten times in the course of two months, in case of a large aneurysm of the arch of the aorta and of the innominate artery. There was no local reaction, but the temperature rose, and five times a transient albuminuria was observed. The patient had entirely lost her dyspnea by the end of the treatment and could run and climb a mountain and do physical work. The relief was so marked that although the injections were painful, yet the patient clamored for them each time.—*Med. Obbsrenye*, August.

Early Signs of Arteriosclerosis.—Cherchevsky states that in normal conditions the diameter of the aorta varies at different times. It becomes dilated if the region over the arch

is struck a few blows with the percussion hammer, while it shrinks in size if the blows are struck in the epigastric region. In case of arteriosclerosis it is impossible to produce these variations in the diameter. The aorta retains the same outlines at all times. Another sign of incipient arteriosclerosis is the lowering of the point in the back where the aortic sounds are most distinct. The subject sits astride a chair with arms crossed. In normal conditions, the maximum distinctness is perceived at the spine of the left scapula. In case of arteriosclerosis, the maximum is perceived at a point on a line between the angle of the scapula and the spinous process of the seventh dorsal, much lower than normal. Cury has been studying this sign which was first pointed out by Friedmann, and found it 89 times in 89 cases of arteriosclerosis, while he only noted it six times in a large number of presumably healthy persons, and 2 have since developed arteriosclerosis.

Mikulicz's Experiences with Carcinoma of the Stomach.—Out of 100 patients treated by resection, 17 per cent. are radically cured; 20 are still living, six months to more than eight years after the operation. The mortality was 37 per cent., and 25 per cent. in the last few years. The average survival is about a year, and patients succumb then usually to some internal, less painful and less distressing metastasis, in the ovary, bone or elsewhere. In 143 cases treated by gastro-enterostomy the mortality was 31.5 and 26 per cent. The patients survived five and a half months on an average, about thirteen and a quarter months after the first symptoms of the disease. Gastrostomy and jejunostomy proved to be merely palliative interventions, undertaken from humane reasons. The mortality after exploratory laparotomy was only 4.5 per cent., and the average survival was twelve months. Mikulicz concludes from these experiences on a total of 447 cases of carcinoma of the stomach observed during the last ten years, and all but 127 operated on, that resection and exploratory laparotomy are the preferable operations, while gastro-enterostomy is indicated only in case of stenosis of the pylorus with stagnation.

The Violet Cure for Cancer.—A paragraph has been going the round of the press, describing how a tumor of a tonsil, the diagnosis of which was "made certain by microscopic examination of a small portion removed," was "cured" by the application of a number of fomentations made from an infusion of green violet leaves. The patient, in gratitude of her recovery, has had printed some leaflets describing the mode of preparation and application of this infusion. We can fully enter into her feelings. She had suffered greatly for four months from a throat affection which was relieved by no treatment. She grew steadily worse and her life was despaired of. The diagnosis of "cancer" seemed to be confirmed by microscopic examination. Within a week of the application of infusions of violet leaves much of the swelling had disappeared and all pain had ceased, and in a fortnight the "cancer" of the tonsil had entirely disappeared. Overjoyed at her own recovery she hastens to make known to other sufferers the marvelous and simple method of treatment, ignorant that already many hopes of recovery have been founded on similar unsubstantial basis. The whole importance of the story depends on the accuracy of the diagnosis of epithelioma. All who are familiar with the clinical signs of a malignant disease of the tonsil can easily believe that it is not difficult to mistake deep-seated inflammation of the region for a malignant growth. As to the microscopic examination, the arrangement of the epithelium of a normal tonsil may easily resemble the epithelial down-growths of an epithelioma, and the resemblance is still more striking when chronic inflammation is present. The history of the case points to a very natural error of diagnosis. The violet leaf, by the way, figures not infrequently among the recipes of the old Anglo-Norman writers whose manuscripts are preserved in the British Museum. In modern pharmacopeias the violet is noted for its cathartic and emetic qualities, or, to speak more accurately, the Viola tricolor or pansy possesses these useful attributes. The dog violet also is vaguely recorded, in an old edition of Balfour's "Botany" (1854), to have been at some time or other prescribed for "skin disease." In the age of the Plantagenets monkish medical writers treated most diseases with the violet, whether dog, pansy, or sweet March they do not state. Intermingled with a multiplicity of other ingredients the modest flower was used to treat "a streytness of the hert," an illness akin, we may suppose, to dyspepsia. It was said to be good also for the stone, and if a broken fragment of bone had to be expelled from the flesh the violet, with other herbs, was considered most useful. Into these old medical mixtures the violet was always introduced in "a good handful" and we are at liberty to suppose that its pleasant perfume, in an age when contrasts were much insisted on, was supposed to work wonders against noisome suppurative ailments.—*London Lancet*, Nov. 23, 1901.

Societies.

COMING MEETINGS.

Western Surgical and Gynecological Association, Chicago, Dec. 18-19, 1901.

Seaboard Medical Association of Virginia and North Carolina.—The next annual meeting will be held in Norfolk, Va., December 17-19.

Tri-County Medical Association of Iroquois, Ford and Vermilion Counties (Ill.)—The annual meeting will be held at Paxton, December 30.

Des Moines Pathological Society.—At the annual meeting of this Society, held November 26, the following officers were elected: Dr. Crayke S. Priestley, president; Dr. Alva P. Stoner, vice-president; Dr. John F. McKitrick, secretary, and Dr. A. Raymond Amos, treasurer.

Eastern Oregon District Medical Society.—The physicians of Umatilla County and Eastern Oregon met for organization at Pendleton, November 27 and elected the following temporary officers: Dr. J. L. Miller, Pendleton, president, and Dr. T. M. Henderson, Pendleton, secretary.

Tyler County (Texas) Medical Association.—A meeting of the practicing physicians of Tyler County was held at Woodville, November 19, when an association was organized, to be known as the Tyler County Medical Association. Dr. William P. Chapman, Woodville, was elected president, and Dr. M. F. Bledsoe, Rockland, secretary.

Duluth-Superior Academy of Medicine.—At the annual meeting of the Academy held at the West Superior Hotel, the following officers were elected: Dr. William E. Ground, Superior, president; Dr. Alfred E. Walker, Duluth, vice-president; Dr. Patrick G. McGill, Superior, secretary and treasurer, and Dr. George H. Conklin, Superior, censor.

New Castle County (Del.) Medical Society.—At a recent meeting of the physicians of New Castle County, at Wilmington, it was decided to organize a county medical society. Drs. Joseph W. Bastian, James A. Draper, Jr., Wilmington, and Harry G. M. Kollock, Newark, were appointed a committee to prepare a constitution and by-laws, and to report at a subsequent meeting.

Northern Central Illinois Medical Association.—This Association held its twenty-eighth annual meeting at Dixon, December 3 and 4. Dr. John Ross, Pontiac, was elected president; Dr. Jane Reid Keefer, Sterling, first vice-president; Dr. William O. Ensign, Rutland, second vice-president, and Dr. George A. Dicus, Streator, secretary and treasurer. The next meeting will be held in Streator.

Minnesota Valley Medical Association,—The annual meeting of this Association was held at Mankato, December 3. The following officers were elected: Dr. William J. Mayo, Rochester, president; Drs. Franklin A. Dodge, Le Soeur, W. J. McCarthy, Madelia, and Edward W. Benham, Amboy, vice-presidents; Dr. Edwin D. Steel, Mankato, secretary, and Dr. George F. Merritt, St. Peter, treasurer.

Grand River (Mo.) Medical Society.—This Society met at Brookfield, Mo., December 5, and several papers of interest were read and discussed. The following resolution was adopted: "Resolved, That the Grand River Medical Society endorses the plan of medical organization as adopted by the American Medical Association and recommended to state and county societies; and that this society urges the Medical Association of the State of Missouri to adopt the plan at its earliest convenience." The following officers were elected: President, George W. Goins, Breckenridge; vice-president, Dr. Cantwell, Meadville; secretary, J. B. Eure, Brookfield; treasurer, J. L. Burke, Laclede, and curator, B. N. Stevens, Chillicothe.

Fox River Valley (Ill.) Medical Association.—The seventy-third semi-annual meeting of this Society was held at Aurora, November 26. Hon. Charles Page Bryan, minister to Brazil, and Dr. Daniel R. Brower, Chicago, were guests of honor. The following officers were elected: Dr. George E. Allen, Au-

rora, president; Dr. George J. Schneider, Elgin, vice-president, and Dr. Henry J. Gahagan, Elgin, secretary and treasurer.

Davenport (Iowa) Clinical Society.—Further steps toward the organization of this Society were taken at a meeting of physicians, and a banquet was held in the Kimball House, November 26, at which Dr. Clarence T. Lindley presided and Dr. Edward S. Bowman acted as secretary. There will be three grades of members, active, associate and honorary. Associate members will be medical students to whom no admission will be charged. The Society will embrace physicians of Davenport, Rock Island and Moline and of the adjoining counties. It is one of its purposes to establish a medical library.

UNIVERSITY OF CHICAGO MEDICAL CLUB.

Second Regular Meeting, held in the Hull Physiology Laboratory, Nov. 4, 1901.

DR. SIDNEY KUH presented the results of observations made in collaboration with Dr. Albert B. Hale. See "Mirror-Writing and the Inverted Image," THE JOURNAL A. M. A., No. 21, vol. xxxvii, p. 1380.

Law of the Innervation of the Frog's Leg.

DR. HENRY H. DONALDSON presented the following findings as evidence of an apparently simple law controlling the distribution of the medullated nerve fibers to the different segments of the leg of the frog (Rana virescens):

The data which are represented by the number of medullated nerve fibers in the various nerves of the leg are furnished by the investigations of Dr. Dunn, part appearing in a paper published under the title of "The Number and Size of the Nerve Fibers Innervating the Skin and Muscles of the Thigh of the Frog (Rana virescens brachycephala, Cope)," and part from a second investigation still in manuscript. In all both legs of three frogs have been examined. In the case of the first two frogs the observations apply to the innervation of the thigh and of the remainder of the leg, whereas in the third case the observations apply to the thigh, shank and foot of each leg.

It was shown, in the first place, that the number of medullated nerve fibers going to the thigh could not be determined by merely subtracting the number below the branches to the thigh from the total number above the branches, because some of the nerve fibers divided, and hence the number actually found in the branches was in excess of the number which had been estimated. In each one of the cases, six in number, this excess was determined and credited to the splitting fibers. With these data the attempt was made to find an hypothesis which should express the number of fibers actually observed to go to the different segments of the leg.

Tentatively, the simplest hypothesis was formulated, namely, that the ventral root fibers were distributed according to the weight of muscles in the different segments of the leg, and the dorsal root fibers according to the area of the skin. To test this hypothesis it was necessary to know, in the first place, the relative weight of the muscles and relative areas of skin in the several segments. By previous investigations these proportional weights and areas had been determined as follows:

TABLE 1.

	Relative Weight of Muscles. Per cent.	Relative Area of Skin. Per cent.
Thigh	64.0	36.5
Shank	24.3	24.9
Foot	11.7	38.6
Total	100.0	100.0

Fortunately the frog's leg does not change in form as it increases in size, and hence these percentages expressing the relative development of the different parts are independent of absolute size of the leg. To apply these percentages, it is necessary to know the relative abundance of the ventral root fibers and dorsal root fibers in the nerve supplying the thigh. This was determined at the level of the dorsal and ventral roots, where it was found that for every 100 ventral root fibers there were present 176 dorsal root fibers. Applying this ratio to the total number of fibers entering the thigh, it was possible to calculate the absolute number of ventral root fibers and the absolute number of dorsal root fibers there present, according to this ratio.

Next, the ventral root fibers were distributed according to the percentage of them called for by the weight of the muscles in the different segments of the leg, and similarly the dorsal root fibers were distributed in accordance with the area of skin. The numbers thus determined for each segment were added together, thus giving the total number of fibers which were, by hypothesis, to be expected in each segment of the leg. The next step was to determine the percentage value of these totals, and it was found that the proportion of the total number of fibers going to each segment was as follows:

TABLE 2.—Proportion of the total number of fibers to each segment of the leg.

	Per cent.
Thigh	46.3
Shank	24.6
Foot	29.1
Total	100.0

This gives us a statement to the effect that 46.3 per cent. of the total number of fibers entering the leg would be found distributed to the thigh and 24.6 per cent. to the shank and 29.1 per cent. to the foot. In each case it is to be remembered that the number of branching fibers is credited to the number which enter the segment of the limb and that the percentage is based on this sum. Under these circumstances the results are found to be as follows:

TABLE 3.

Frog.	Segment of leg.		No. of Medullated Fibers Observed.	Calculated.	Differences Based on Observed No. Absolute.	Per cent.
B	Thigh	r	2623	2542	+81	+3.0
"	"	l	2600	2580	+20	+0.7
C	"	r	2814	2862	—48	—1.7
"	"	l	2777	2860	—83	—3.0
II B	"	r	3508	3449	+59	+1.6
II "	"	l	3481	3446	+35	+1.0
II B	Shank	r	2130	2119	+11	+0.5
II "	"	l	2108	2106	+ 2	+0.1
II B	Foot	r	2497	2508	—11	—0.5
II "	"	l	2486	2492	— 6	—0.2

The very close approximation thus exhibited between the calculation and the number observed, completely supports the original hypothesis, and this leads to the formulation of the law in the following terms:

If the dividing fibers in each segment of the leg are taken into account, then the observed number of medullated fibers innervating a given segment of the frog's leg is equal to the number calculated on the hypothesis that the efferent fibers are distributed in proportion to the weight of muscle and the afferent in proportion to the area of the skin. It is to be noted in conclusion:

1. That this law at the moment is applied to the frog's leg only, and is not extended to higher vertebrates.

2. That although in the terms of this hypothesis the afferent fibers are distributed according to the area of the skin, yet this is by no means equivalent to the assertion that the afferent fibers are all cutaneous fibers, for we have every reason to think that very many of these fibers are distributed to other portions than the skin.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, held Nov. 7, 1901.

Dr. Herman Knapp, Vice-President, in the Chair.

The Causation of Multiple Neuritis.

DR. M. ALLEN STARR presented a paper on this topic. Speaking of arsenic, he said that arsenical multiple neuritis had often resulted from the use of toilet powders containing this substance, as well as from the inhalation of arsenic from colored wall-paper. He had himself seen a remarkable case exemplifying the latter source of arsenical poisoning. Ar-

senic had also been found in beer, having found its way into that beverage through the use of glucose made from sulphuric acid derived from pyrites containing arsenic. In these days when copper is so extensively used for electric purposes it was not unreasonable to find arsenic poisoning in workers who use copper containing arsenic as an impurity. In some factories, notably those making copper for electric purposes, it is found necessary to expel the arsenic from the copper. This is done by the application of heat, and although the fumes are conducted to the tops of tall chimneys the workmen are very apt to suffer from arsenical neuritis. Workers in potteries are apt to be affected by the lead used in the manufacture of these goods, and it should not be forgotten that lead is also an ingredient of the glaze found on earthenware kitchen utensils, and that in this way it sometimes gets into food. With the modern methods of making mirrors the danger of mercurial poisoning is largely eliminated, and it is rare indeed that multiple neuritis arises from the medicinal use of mercury. This metallic poison is, however, used in England for producing the gloss on silk hats, so that persons engaged in this industry may fall victims of mercurial poisoning.

Turning from this class of cases to those resulting from poisoning by non-metallic substances, Dr. Starr said that prominent among this group of etiologic factors stood alcohol, and it should always be borne in mind that it was not alone the quantity of alcohol imbibed but the individual susceptibility to the effects of alcohol that must be reckoned with. Coal gas was well known to give rise to neuritis, but it was not so generally known that the same is true of natural gas, and that neuritis has become much more common in districts making a general use of this gas for fuel. Now that the manufacture of rubber tires had become such an important industry in this country it behooved physicians to be on their guard for cases of multiple neuritis arising in rubber workers from inhaling the fumes of bisulphid of carbon. Neuritis may also arise from the use of certain drugs of the coal-tar series, notably from antipyrin, acetanilid, sulfonal, trional, and chloretone and trional.

Another important class of cases of multiple neuritis includes the neurites arising from toxemia, familiar examples of which were to be found in connection with diphtheria, grip, typhoid and typhus fever, scarlatina, measles, mumps, whooping cough, smallpox, pneumonia, gonorrhea, puerperal and other forms of septicemia. Some of the cases of neuritis thought to be directly dependent on typhoid fever were no doubt the result of the free use of alcoholic stimulants during the course of that disease. Neuritis may also arise in connection with various dyscrasias, such as rheumatism, gout, diabetes and arteriosclerosis. It is probable that syphilis is not generally a factor in the causation of multiple neuritis. There were in addition to the foregoing a certain number of cases of multiple neuritis that, because of our lack of knowledge, must still be classed as idiopathic.

DR. C. L. DANA said that he preferred to divide cases of multiple neuritis into three broad classes: 1, those due to toxic causes; 2, those dependent upon dyscrasias, and 3, those resulting from infection. Cases belonging to the third class were characterized clinically by motor phenomena, while those dependent upon dyscrasias were largely of the sensory type. Most persons afflicted with neuritis are neuropathic, and often a so-called alcoholic multiple neuritis was the result of a very moderate indulgence in alcohol together with the excessive use of tobacco. According to his own statistics, alcohol was the cause of two-thirds of all the cases of multiple neuritis, though in the class of women found in our hospitals tea-drinking is an important causal factor.

DR. B. SACHS deplored the growing tendency to diagnose cases of multiple neuritis as alcohol upon a very slender basis of fact. This diagnosis should not be made unless the neuritis coexists with other symptoms of chronic alcoholic poisoning. He had seen multiple neuritis in children living in the swampy districts of Long Island, and proved to be suffering from malarial poisoning. In only one instance had he met with syphilitic multiple neuritis, and in this one the diagnosis had been made purely by exclusion, and its correctness had been confirmed by the results of treatment. He was surprised that Dr. Starr seemed to think diabetic multiple neuritis so rare, for he had not found it so.

DR. FRED PETERSON remarked that in cases of alcoholic multiple neuritis there was often a peculiar mental state characterized by a loss of the sense of time and place. He reported, as an example of the uncertainty of action of chloretone in tablet form, a case in which a young girl had swallowed without appreciable effect 25 five-grain tablets of chloretone.

DR. JOSEPH COLLINS thought diabetic multiple neuritis was comparatively common; it had certainly been so in his experience at the City Hospital. He had met with several cases of tuberculous neuritis, and had seen three cases in which investigation had seemed to prove that the neuritis had resulted from lead poisoning, the lead having been taken into the system through the use of snuff that had been packed in a leaden casing.

DR. HERMAN KNAPP thought the term neuritis had been used in this discussion without any histologic basis for the implied existence of an inflammatory process. While it was true that an optic neuritis could be actually seen after the grip, it was not true that tobacco gave rise to any such inflammation in the eye, for, in cases of tobacco amaurosis one sees with the ophthalmoscope no evidence of inflammation, but only of an atrophy.

CINCINNATI ACADEMY OF MEDICINE.

Regular Meeting, held Oct. 28, 1901.

The President, Dr. N. P. Dandridge, in the Chair.

Fetal Chondrodystrophy.

DR. ALBERT FREIBERG presented this case. It was noticed soon after birth that the child's thighs and legs were much bent and that they were apparently tender on manipulation. The same could be said of the upper extremities, although in less degree. An examination of the child showed none of the evidences of rickets in its classical form. There was no beading of the ribs; there was nothing abnormal in the formation of the skull and the tenderness of the long bones was not confined to the epiphyseal regions, but well marked over the diaphysis in each case. The child did not present any of the characteristics of congenital syphilis. It cried almost incessantly during the first two weeks of life, but afterwards seemed comfortable. The child disappeared from his observation and was not seen for several months, and then at the Jewish Hospital. Without having accurate measurements upon which to base the statement, it appeared to him that the child's extremities had not, at the time of the second examination, grown to a degree commensurate with the growth of the trunk. Aside from this he could see no change of importance. There seemed to him no doubt but that in this case there existed the rather unusual condition known as achondroplasia, or by the better term of chondrodystrophy. It is the condition which is now considered responsible for many of those examples of onanism with great deformity found in anatomical museums; it is a condition which runs the greater part of its course during intra-uterine life, for at birth the activity of the process has for the most part come to an end. The disease affects chiefly the long bones, therefore those developed from cartilage. Bones developed from membrane are rarely affected. Anatomically the disease consists of an interference with the activity of the epiphyseal cartilages. The periosteum retains its osteoplastic activity. It follows, therefore, that while the length is greatly reduced, the transverse diameter of the bone is practically normal. In rickets we have the bones of normal length with curvatures not much accentuated until they have borne weight; in chondrodystrophy, on the other hand, the bones are shortened, thicker than normal, and often greatly curved even at birth. According to Regnault, it is possible by the examination of the skeleton of the adult to say whether the condition which produced the deformity was rickets or chondrodystrophy. In chondrodystrophy the bone is shortened, thickened, and all of its normal prominences are exaggerated, but the bone is not

necessarily curved at all. In rickets the curvature of the bone is not accompanied as a rule by shortening. We are familiar with this fact clinically. According to Turner the essential anatomical change is located at the epiphyseal line. The columnar arrangement of cells normally present here in growing bone is defective or even absent; there is a fibrous ingrowth of periosteum at this point, so that cartilage cells can not develop into the normal osseous areolæ. The epiphyses increase, it seems, by irregular and excessive growth of the perichondrium. The periosteum continues to grow, and the bone is therefore much thickened and of irregular shape. Turner believes that the condition of rickets in utero is unknown and he therefore objects to the terms congenital and fetal rickets, it would appear, with much reason. The clinical importance of these cases of chondrodystrophy lies in recognizing the nature of the disease and its prognosis. It has been essayed to treat the condition by thyroid medication, but without result. These patients seem condemned to the condition of dwarfism, and it is well that the parents should be informed of this at not too late a period. If any attempt is made to overcome the deformity of the bones and particularly if the operative method is chosen, it should be made clear that they will be lengthened only, inasmuch as the curves are straightened, and they will nevertheless continue to be shorter than normal. It is otherwise conceivable that the shortening might be attributed to the fractures or osteotomies as the case may be.

Gunshot Wound of the Abdomen.

DR. N. P. DANDRIDGE said that the young boy came into the Cincinnati Hospital June 9, 1901, having shot himself only a few minutes before with his father's pistol. The pistol was a 32-caliber. There was an abdominal wound of entrance and a wound of exit, and the wing of the ileum was furrowed by the ball. The boy was brought into the hospital, and was considerably shocked, but not profoundly so. The pulse was accelerated, but not irregular, and was quite perceptible. Operation was decided upon at once, and the boy was on the table within an hour after the accident. The intestines were taken out and three wounds in the small intestine were at once discovered, two of these being within 3 or 4 inches of the point of entrance of the bullet. The loop containing the wounds was taken out and sutured. Upon further examination it was discovered that there was an opening into the stomach on the anterior wall and also one on the posterior wall. In the stomach was quite a quantity of semi-digested food, and there had been a slight amount of leakage from that organ. The wound on the posterior wall was smaller than that on the anterior and there was no eversion of the mucous membrane in this perforation as there was in the wound of the anterior wall. Four other perforations were discovered in the intestines, making seven wounds of the intestines, besides the wounds of the stomach. The point at which the bullet passed out of the abdominal cavity was not discovered. I make mention of this fact because I think from the sequela of the case that perforation of the large intestine may have occurred. The boy made a satisfactory recovery. The temperature on the day after the operation was 102, and after that ran along at about 100 until the 16th day, when it suddenly went up to 103, and there was a discharge from the external wound of a quantity of foul pus. Two days after the accident there was a discharge of blood from the bowel, which continued for several days. A sinus persisted at the point of entrance. This was opened up and a portion of the bone that had been injured by the passage of the bullet curetted. The wound then healed up promptly and the boy left the hospital on the 40th day after the injury. He is in perfect health and does not suffer from the wound.

Cardiac Specimens.

DR. O. P. HOLT presented a specimen of tumor of the ventricular wall of the heart, situated near the apex. The tumor was about the size of a small lemon, and microscopic examination showed that it was completely surrounded by muscular tissue. Examination also showed the mass was an organized blood clot; there was thrombosis of the anterior coronary artery and the latter was also very markedly sclerotic. The hemorrhage could be readily traced to the rupture of this artery. The symptoms of the case were those of organic incompetency of the mitral valves. The case was from an adult male, aged but 31. The pathological report was made by Dr. H. J. Whitacre.

DR. G. A. FACKLER presented, in this connection, a specimen of acute suppurative myocarditis in which the condition was unsuspected during life, the symptoms having been masked by a pneumonia.

DR. J. E. GREIWE presented a specimen of diseased heart in which there was a fibrous ring completely surrounding the aortic ring and extending up into the aorta. The beginning of the aorta was the seat of incipient aneurysm. The case was interesting in connection with Dr. Holt's, showing two distinct phases of relative incompetency, yet both dependent upon underlying arterio-sclerotic processes.

MEDICAL SOCIETY OF RUSH COLLEGE.

Regular Meeting, held Nov. 4, 1901.

Pathological Specimens.

DR. LUDVIG HEKTOEN presented the following two specimens: 1. Stricture of membranous urethra, ascending gangrenous inflammation of the entire urinary tract: The stricture was located a few centimeters from the meatus. Owing to the obstruction great dilatation of the bladder, the ureters and the renal pelves had resulted, followed by a violent necrosis and gangrene of the entire mucous membrane, which presented a rough, shreddy and dirty grayish appearance. There was present in characteristic form the necrosis of the apices of the medullary pyramids seen in recent dilatation of the renal pelvis and attributed generally to pressure. At the autopsy (Dr. Wells) the turbid, foul urine in the bladder was covered by a layer of liquid fat, which probably came from the extension of the destruction to the fat at the hilum of the kidneys. No other source for the fat was found. The patient entered the Cook County Hospital in coma and died soon after so that exact facts as to the previous occurrences were not obtainable.

2. Healed ulcerative endocarditis of the aortic valves: Two specimens were presented of hearts, in each of which one aortic valve showed a large rounded perforation, with smooth but thick and sclerotic margins, about 1 cm. in diameter, situated in the substance of the valve between the line of closure and the base. There was in each case general sclerosis and deformity of the aortic valves, the result of endocarditis, and in one case an acute destructive process was engrafted upon the chronic. The size, the location, the character of the margins of the perforations as well as the several scleroses of the valves led to the conclusion that it concerned healed ulcerative processes, which probably had caused valvular aneurysm with perforation, and that the specimens afforded anatomic evidence of the healing of ulcerative endocarditis, a possibility the occurrence of which is supported by clinical observations.

Two Cases of Ocular Paresis Presenting Unusual Clinical Pictures.

DR. F. C. HOTZ said that paralysis of any ocular muscle causes a deflection of the visual line of the affected eye (strabismus) and diplopia, which is especially noticeable when the eyes are turned in a direction requiring the co-operation of the affected muscle. Under ordinary circumstances these symptoms (strabismus and diplopia) make correct diagnosis an easy task. But the diagnosis becomes a perplexing problem if the patient prefers using the affected eye, perhaps because it has much better vision than the other eye, or for some other reason; for as soon as the affected eye is made to look straight the other eye will show a marked strabismus. In these cases the diplopia tests are exceedingly valuable for the diagnosis. To illustrate, he described the following cases:

CASE 1.—Salesman, 37 years, presented himself with a marked convergent squint of the right eye and homonymous diplopia, which had come on about two weeks ago; cause unknown. Apparently paralysis of the externus of the right eye;

but the double images came together when the light was moved to the right, and they separated when it was moved to the left. Homonymous lateral diplopia indicates paralysis of the externus and the separation of the images towards the left points to the externus of the left eye as the affected muscle. The diagnosis was confirmed by the fact that the abduction of the right was normal, while the abduction of the left eye was greatly restricted.

CASE 2.—A workman, age 38, was struck over the left eye and six weeks later began to see double. The left eye is straight, the right eye is turned down and in. It looks as if the right eye could not be turned up—paralysis of its superior rectus or inferior oblique—but the diplopia test shows the image of the right eye above and to the right of the image of the left eye, the images separating in the upper field and coming together in the lower field. This test plainly shows that the downward movement of one eye is restricted, hence that the affected muscle is one of the depressors—inferior rectus or superior oblique. Homonymous images point to the superior oblique and the image of the left eye, being lower, points to the left eye. Hence the correct diagnosis is paralysis of the superior oblique of the left eye.

Epitheliomata.

DR. WILLIAM H. WILDER showed a man, 71 years of age, who, seven years before, had had an epithelioma removed from the lower lip. A short time ago, epithelioma developed in the upper inner part of the right orbit, involving the eyeball. The case is under treatment by Dr. Pusey with the *x*-rays.

He also showed a case of a man, 51 years of age, from whose right cornea he had removed an epithelioma. Recovery of perfect vision followed the operation. He also showed two specimens of epithelioma of the cornea, one of which was situated on the limbus and the other wholly within the cornea.

Sarcoma of Iris.

DR. A. B. HALE presented a case of a young woman of 22, from whom he had removed a sarcoma of the right iris. The tumor was detected less than three weeks after symptoms of pain had appeared and had been promptly excised—seemingly in a capsule. The microscope confirmed the diagnosis, and the history of the case, together with the subsequent behavior of the eye, which was now, six months after the operation, perfectly normal, indicated a primary sarcoma of the iris without recurrence. (Microscopical specimens were exhibited.)

Dr. Hale also demonstrated an eyeball enucleated 60 hours after a penetrating wound with a piece of steel from a hammer. The path of the foreign body through the lens to a bed in the choroid anterior to the equator was plainly visible. The eye had shown no inflammatory reaction, but an *x*-ray photograph was positive. He acknowledged the progress made during recent years in diagnosis and treatment without the destruction of the eyeball, of such cases, but in view of this patient's age, namely, 77, and the unavoidable danger from delay, enucleation had been promptly done with the full consent of the patient.

SAN FRANCISCO COUNTY MEDICAL SOCIETY.

Regular Meeting, held Nov. 12, 1901.

Ectopic Pregnancies.

DR. J. HENRY BARBAT exhibited some pathological specimens. The first specimen was one of a "Tubal Pregnancy Resembling Appendicitis," in a woman 19 years of age, who menstruated at the regular time, but suffered unusual pain in the lower part of the abdomen. After flowing the regular number of days she ceased for four days and then began again, the flow coming on with sudden pain in abdomen; vomiting and tenderness over the right side; bimanual examination was negative; uterine scrapings did not show any decidual cells. The day after curetting laparotomy was performed and the appendix found coiled under the cecum and presenting a peculiar thickening near the distal end, which was cicatricial due to an appendicitis obliterans. The right ovary and tube were palpated and found normal, the left ovary was normal and the left tube, which could only be felt for about three-fourths of its distance, was apparently free and did not feel larger than the right. No blood was found in the pelvis, so the abdomen was closed. Occasional attacks of pain followed the operation, and two weeks subsequent an exceedingly tender mass was detected on the left side of the uterus. The patient had slight flow ever since the curetting and another laparotomy was performed when the pelvis was found full of blood clots with the left tube distended at its distal end and bleeding through a rupture close to the fimbriated extremity, which was removed close up to the uterus. A fetus, at least seven weeks old, was found in the blood clots. Recovery was uneventful. The case illustrated the difficulties which sometimes present themselves in ectopic pregnancy, and showed how much suspicion must be attached to a renewal of the menstrual flow after it had stopped for several days, especially if it continued and was accompanied with pain and tenderness in the abdomen.

The second specimen was also one of "Tubal Abortion" and was the result of operation on a woman 28 years of age who forty days after her last menstruation, flowed for two weeks. This ceased for three or four days and then began again; she had intermittent attacks of pain which, on one occasion was so severe that it made her feel faint. Physical examination revealed a mass three inches in diameter in the cul-de-sac, very tender and evidently connected with the right side of the uterus. Tubal abortion was the diagnosis and operation done the next morning. The pelvis was filled with a soft boggy mass, strongly adherent to the posterior wall of the uterus, and which proved to be the right tube, and was removed, leaving about one inch of normal tube. The left tube was adherent and thickened at its middle, occluding its lumen and so was removed also. The patient went home at the end of three weeks perfectly well.

The specimen from the right tube proved to be a tubal pregnancy in the seventh or eighth week and had been extruded from the end of the tube with the placenta and a large clot of blood, which was still strongly adherent to the fimbriated extremity.

President's Address.

DR. GEORGE H. EVANS, the retiring president, read a paper in which he made some recommendations for the future policy of the Society. The work done by the Society during the past year, which was very satisfactory, was then reviewed. The plan of having two or more papers, taking up different phases of the same subject, was commended, but it was to be hoped that in the future more attention would be paid toward getting clinical reports. The increase in membership had been satisfactory. The membership at the present time being 37 per cent. of the entire regular registration of the county, which the writer thought was a larger proportion than existed in any large city in the country. The membership could be increased very materially if the method by which applicants gained entrance was changed. Membership should depend either on a majority vote of the Society or on the vote of the Committee on Admissions alone. The co-operation of the smaller local societies could also increase the membership. There should be no rivalry between this body and any other local societies, for their purposes were not identical. Membership in the others should be contingent on membership in the County Society. All methods whereby membership could be increased, should be urged, for it was only through the thorough organization of the County Society that the beneficent objects of the reorganization plan of the American Medical Association can be consummated and the profession united into "a compact organization reaching into every county in the Union." Harmonious action between this Society and the Committee on Reorganization of the State Society was urged. Attention was called to the value of the library, which was not used by the members as much as it should be. A great many additions had been made during the year, but more journals, especially foreign ones, were needed; also such textbooks as were beyond the reach of some of its members. The writer thought that a larger proportion of the funds should be used freely for this purpose. A change in the constitution

should be made, providing for a standing committee on public health, which should take up measures looking toward the education of the laity in such matters. This he thought was clearly one of the duties of medical societies which had been too much ignored in the past. Such a committee could also undertake an investigation of the milk supply, after the plan of the Milk Commissions of the Philadelphia Pediatric Society and the New York County Medical Society. Such work was needful. A committee of medical legislation should be also created. The state medical bill which recently passed the legislature had been strongly opposed, and such legislation should have an active committee in the Society to protect and father it; for those whose selfish interests were adversely affected by this bill would undoubtedly be interested and watchful for an opportunity of seeing it repealed or amended. Medical charities and medical contract work should engage the serious attention of the Society, for their effects had proven pernicious.

The following officers were elected for the ensuing year: President, John C. Spencer; first vice-president, R. L. Rigdon; second vice-president, M. Krotozyner; recording secretary, W. F. Barbat; treasurer, F. R. Dray; librarian, Vard H. Hulen.

DENVER AND ARAPAHOE MEDICAL SOCIETY.

Regular Meeting, held Oct. 22, 1901.

The President, Dr. H. G. Wetherill, in the Chair.

Tuberculosis in Colorado.

Dr. S. E. Solly, Colorado Springs, spoke on this subject. He said the first case of tuberculosis originating in Colorado was brought to his attention some years ago by Dr. Meigs, of Philadelphia, who had a patient, a miner, under his treatment in the Philadelphia Hospital. He himself has seen only one case. It was in a boy, 17 years old, who lived in Colorado for seven years. There was no tuberculosis in his family. He had no doubt that the disease in this case originated in Colorado. He had seen in consultation a child that suffered from meningitis and tuberculosis of the lungs. Neither the neighboring children nor the parents suffered from tuberculosis. He knows of another case, a plumber, who hired a helper suffering from consumption of advanced stage. The plumber slept with his help in the same bed. Eighteen months after the first hemorrhage he died. Dr. Solly recited several other cases of tuberculosis, originating in Colorado, which were mentioned to him by Drs. Strickler, Nash and others. He is convinced that tuberculosis can develop in Colorado. He believes the germ of tuberculosis is omnipresent, and can be developed under favorable conditions. No matter that indigenous cases are but few in Colorado, it is still a question to which the profession should devote a great attention. He believes registration to be a good thing, but the disease spreads not alone from private houses, but from hotels, workshops, offices, etc. All efforts should be directed toward educating the people in matters of public and private sanitation.

Dr. J. N. Hall said that he reported five cases of tuberculosis originating in Colorado some five years ago. Since that time he has seen fifteen cases during his service in the County Hospital, the clearing house of consumptives.

Dr. Wm. P. Munn related the history of three cases originating in Colorado: A man in perfect health who developed tuberculosis of the spine and then of the lungs after his tuberculous nephew sojourned in his house for one year. The other was a young woman who developed tuberculosis during her pregnancy. The infection in her case was traced to carpets bought of a tuberculous patient. The third case was a woman who worked in a store in proximity to two men suffering from tuberculosis. As to prophylaxis, every man has a right to seek a place where his health will be restored, but society has a right to demand of him to conform to conditions which tend to lessen the danger of infection.

Dr. G. E. Tyler had seen during the last three years about 10 cases of tuberculosis originating in Colorado. While filing the mortality statistics of Colorado he noticed that the majority of the indigenous cases originate not in large cities, but in mining camps. He made some investigations and ascertained that these cases begin as miner's consumption and become eventually tubercular. It is said that it is caused by the material used in blasting.

Dr. C. B. Richmond said that during the early period in Colorado the miner worked at the surface. Now a depth of 2000 feet is reached. The miner passes eight hours underground, eight hours in the saloon and eight hours in a small, dirty and ill-ventilated room. It is lack of oxygen that causes trouble in the tenement houses as in the camps.

Dr. E. P. Hershey related a case in which direct exposure could not be traced. A lawyer in opulent circumstances with no bad habits came down with what was at first believed to be typhoid fever, but proved eventually to be rapid consumption.

Dr. Leonard Freeman encountered a case of tuberculosis of the testicle in a ranchman, which developed in Colorado.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

PRESCRIPTION WRITING, V.

(Continued from p. 1556.)

The frequency of administration, which is the third important point mentioned above, will be more conveniently considered later along with the fugitive and cumulative action of drugs.

Idiosyncrasies Toward Drugs.

As a rule male patients bear larger doses of medicine than female. However, in either sex idiosyncrasies are manifested when certain drugs are given. For the sake of illustration, mention may be made of certain untoward symptoms produced by the following drugs:

Quinin sulphate produces very readily, in some individuals, the pronounced ringing in the ears, in others nausea, and in others again it produces a marked eruption over the body. The hydrobromate of quinin is sometimes tolerated in such cases as the above, and by giving the bisulphate hypodermically the nausea can be eliminated. We speak of giving the quinin bisulphate hypodermically because it is the most soluble salt of the alkaloid, being soluble in about 15 parts of water.

Potassium iodid can not be tolerated by certain susceptible individuals, as it causes headache in some, and in others the marked eruption on the skin even though given in small doses. It may be accompanied by other symptoms of iodism.

Strychnin sulphate induces occasionally an increased degree of nervousness; susceptibility is rare when we consider that in the form of nux vomica it is given as much or more than any other drug in the pharmacopeia.

Arsenic also has to be carefully administered and the patient closely watched on account of poisonous symptoms developing in certain cases after the use of even very small doses of the drug. Vomiting may occur, due to its effect upon the stomach. Arsenic is better tolerated when prescribed in the form of Fowler's solution and given well diluted in water.

Cocain, when applied locally to the membranes of the nose or mouth, even in dilute solutions, will cause dizziness and fainting in some cases, whereas 10 per cent. solutions may be applied several times in others with scarcely more than a full sensation in the head.

Opium may act in various ways. This may be due to the fact that it has many alkaloids, the three most important of which are codein, morphin and thebain, each having an entirely different action. As Brunton puts it, they form a chain, at one end of which is a convulsant and at the other a powerful hypnotic. Thus, some susceptible individuals may be peculiarly influenced by the convulsant and others by the powerful hypnotic.

Chloral is another drug which although physiologically a

sleep-producer will in certain cases bring on delirium and general cerebral excitability.

The administration of iron in its different forms may produce a sensation of fulness in the head which is an unpleasant feeling to the patient.

Dwelling a little longer on the idiosyncrasies, it will be of interest to relate the action of some of the foregoing drugs on animals as contrasted with their action upon the individual. This is due in the majority of cases to the lack of development of the nerve centers and nervous system generally in animals. The general class of emetics will not produce vomiting in the rodent animals. A rabbit is not susceptible to effects of morphin, it being capable of withstanding thirty or forty times the amount of the human adult dose. Atropin exercises no influence on the heart of the rabbit. In birds, in which the temperature is much higher than in mammals, morphin produces no hypnotic action, but it has a marked antipyretic effect. Snails are said to withstand much larger doses of strychnin than man, easily explained, however, on account of the low developed nervous system in that mollusc.

(To be continued.)

Treatment of Stricture.

It has been recommended by Bazy, in *Med. Rec.*, to apply the following in treatment of stricture:

℞.	Potassii iodidi	ʒi	4
	Lanolini		
	Ung. aq. rosæ, āā	ʒiv	16

M. Sig.: Apply for five minutes daily to the perineo-bulbar region.

Treatment of Alopecia Areata.

Laboraud, in *Jour. des Pract.*, recommends that the head be shaved, followed by frictions with a medium toothbrush moistened with the following:

℞.	Hydrarg. chloridi corros.	gr. iii	20
	Acidi acetici	gr. xxx	2
	Alcoholis	ʒv	160
	Etheris (officinalis)	ʒi	32
	Saponis (coal tar)	ʒi	32
	Salol	gr. viiss	5

M. Sig.: Apply locally with friction.

In case of increased activity, at any point, the part should be touched with a pledget of cotton moistened with the following:

℞.	Acidi acetici	gr. xi	70
	Chloralis hydratis	gr. lxxv	5
	Etheris (officinalis)	ʒi	32

M. Sig.: Apply locally.

Treatment of Goiter.

Dr. A. Meyer, as noted in *Deut. Aertzt. Ztg.*, states that since iodin has been recommended in sclerosis of the middle ear, he thought he would give it a trial in this affection. The patient had besides ear trouble, an enlarged thyroid gland the size of one's fist. While no improvement could be noticed in the ear affection, the goiter at once began to diminish until it disappeared altogether. He then tried it in another case with as good results. The 10 per cent. iodipin was given in teaspoonful doses three times a day. No untoward effects from its administration were noticed.

Treatment of Simple Chancre.

The following is recommended by Hallopeau and Lereddi, according to *Amer. Med.:* The chancre should be washed with hot sodium bicarbonate solution. All crusts and pus should be removed and the surface cauterized with the following:

℞.	Alcoholis (60 per cent.)	ʒiiss	10
	Acidi carbol.	gr. xv	1

M. Sig.: Apply locally every second day.

Or

℞.	Zinci chloridi	gr. xxx	2
	Aq. destil	ʒv	20

M. Sig.: Apply locally and repeat in two days.

The dressing should be completed by an application of iodoform, bismuth, salicylate or bismuth subgallate. If phimosis exists, the patient should be instructed to inject an antiseptic wash between the prepuce and the glans several times a day, and especially after urinating. For this purpose, solutions of corrosive sublimate, 1 to 200, may be employed. The washings should be followed by an injection of liquid vaselin saturated with iodoform.

Treatment of Otorrhea.

The following is recommended by Botey, as stated in *N. Y. Med Jour.*, for the treatment of otorrhea:

℞.	Ferri chloridi	ʒss	2
	Alcoholis	ʒi	4
	Aq. destil	ʒi	4

M. Sig.: Three or four drops to be instilled into the external auditory meatus two or three times daily.

Treatment of Tonsillitis.

The following is advised by Dantzler in *Med. Record:*

℞.	Tinct. guaiaci ammon.	ʒvi	24
	Tinct. cinchonæ co.	ʒvi	24
	Pot. chloratis	ʒii	8
	Mellis	ʒvi	24
	Acaciæ, q. s.		
	Aq. q. s. ad	ʒiv	128

M. Sig.: A teaspoonful used as a gargle in a little water three or four times a day, and swallowed one-half to one teaspoonful three times a day.

Orthoform to Mitigate Odynophagia.

Dr. S. Solis-Cohen, Philadelphia, states that for temporary relief of the pain attending inflammatory and ulcerative affections of the throat, orthoform applied in various ways is probably the best agent now at our command. For two years he states that he has been using lozenges containing from grain 1/8 (.008) to grain 1 (.06) each of orthoform in cases of acute and subacute sore throat (tonsillitis, pharyngitis) whether of rheumatic or other origin, and in cases in which pain in swallowing has been caused by ulceration or infiltrative conditions involving the epiglottis and arytenoid eminences. In some cases adrenal extract has been used at the same time. He states that this treatment has afforded such relief as to enable the patient to eat with comparative ease. The improvement has been especially noticeable in cases of tubercular laryngitis in which he prescribed the orthoform lozenges ten minutes before meals; it permitted the patient to take the food with a minimum discomfort. The advantage of the lozenge over insufflation or other methods of application is that the patient can himself make use of the analgesic agent.

Medicolegal.

Liability of Physician in Local Option Territory.—The Court of Criminal Appeals of Texas says, in McLain vs. State, that the legislature, as it holds that it had a right to do, has provided that for medicinal purposes intoxicants can only be sold upon a prescription certifying that a regular physician signing the prescription has personally examined the party to whom the prescription is given, and that he is actually sick: and he must certify these matters upon his honor. This is the character of prescription required by the legislature. There is no kind of prescription authorizing the sale, except that provided by statute, and it is not a prescription until it has complied with the law. Where a sale occurs, an illegal prescription is no protection to the seller or the physician, because in that event the physician makes himself a party to the sale by giving an illegal prescription by means of which the law is evaded. As in misdemeanors all are principals, so, when a physician gives an illegal prescription under which a sale occurs, he is as much responsible for the sale as is the seller. Whenever a sale in a local option territory is brought about by means of an illegal prescription, the physician and seller are both liable. Each is required to know the law; each is required, in order to bring about the sale, to comply with the terms of the law; and, in failing, both are liable for the punishment prescribed for illegal sales. The court adds that it is not discussing the attitude of the physician who gives a false

certificate, though in exact terms of the law. He may be guilty of the sale. In this case the court holds that a prescription was properly excluded because not in conformity with law, having omitted the expression "personally examined," and the certificate upon honor, required by the statute.

Mental Soundness of Eddyites.—The Surrogate's court of New York County holds, in re Brush's will, that, however opposed the teachings of "christian science" may be to the beliefs or notions of others, being founded on the religious convictions of those professing them, the court can not say that those persons who hold them are mentally unsound, the truth or falsity of a religious belief being beyond the scope of a judicial inquiry. Thus, the court says it has often been asked to pass upon the falsity of spiritualism, and to hold that a follower of that faith, which, like Eddyism, is contrary to the convictions of most men, was of necessity laboring under an insane delusion; but it has uniformly refused so to declare or hold. The only question which concerns the court, in determining the testamentary capacity of a "christian scientist," is as to the effect of the belief in it on, say, his or her mind, the belief itself not being any evidence of insanity. Did it unseat her judgment, dethrone her reason, and thus deprive her of capacity to make a will? If it did; if, by reason of the effect of this belief on her mind, she became the victim of insane delusions, from which her will resulted, then the will must be set aside. But, in this case, the court is of the opinion that the decedent was of sound mind at the time she executed the will contested.

Opinion Evidence on Survivorship—Presumptions.—In the case of Southwell vs. Gray a husband and wife were found dead in the same bed at their home. The Supreme Court of New York, special term, Erie County, says that death in each case was due to natural gas poisoning. Both were alive on the preceding night. It was assumed that the inhalation of poisonous gases, which escaped during the night from a stove in the room, burning natural gas, effected their death. Upon the trial an effort was made to establish that the husband died first. Evidence was given as to the physical condition in life of each of the deceased persons, the postmortem appearance and condition of the bodies, and the position of the bodies when found with reference to the stove and the windows and walls of the room, and a hypothetical question embracing the facts so testified to was submitted to several physicians for their opinion as to who survived. The physicians called by the one side expressed the opinion that the husband died first. An equal number of physicians called by the other side testified that it was impossible upon such data to express an opinion upon the subject of survivorship with any reasonable certainty. The court, after careful consideration, but without discussing the reasons assigned by the various medical witnesses for their answers to this question, reaches the conclusion that it would be mere conjecture, surmise, and speculation to essay the decision of survivorship in this case upon such testimony. Wherefore, it holds that the case must be determined upon the assumption that there was no proof to decide which of these individuals predeceased the other. Under such circumstances the civil law, the court goes on to explain, indulges in presumption based on age and sex to aid in determining the survivorship of persons perishing in a common disaster. The common law, however, recognizes no presumptions on the subject. In the absence of evidence, the fact is assumed to be unascertainable, and a rule of distribution has been adopted whereby property rights are disposed of as if death occurred simultaneously.

X-Ray Photographs—Notice of Taking.—The Supreme Court of Wisconsin holds, in the personal injury case of Mauch vs. the City of Hartford, that the rule in regard to the use of ordinary photographs upon the trial of a cause, for the better understanding by the jury of the evidence or the merits of the case, applies to photographs taken by the aid of *x*-rays. Whether a photograph is proper or not in any particular situation upon the trial of a case is a matter within the sound discretion of the trial judge, and his determination can not be disturbed if there was any reasonable ground therefor. Here, a surgeon who qualified as an expert as regards taking *x*-ray photographs, testified to having examined the bones of the injured party's arm, wrist and hand by the *x*-ray process, and taken two photographs thereof which correctly represented such bones. The witness produced the photographs, and they were offered and received in evidence against the city's objection. The ground of the objection was that the photographs were not taken upon notice to the city or its counsel. The Supreme court, however, says that it knows of no rule rendering notice of the taking of a photograph, to be used by one party on the trial of a cause, to the adverse party, so that the latter may be represented at the time of such taking, essential to its reception in evidence. The use of photographs in the trial of causes for some purposes, and among them that of exhibiting for the better understanding of the jury particular objects, is permissible where there is some substantial reason therefor. The purpose of exhibiting a photograph to court and jury is to enable them to more clearly understand the appearance of a particular locality or object material to the litigation than could ordinarily be expected from mere oral descriptions and explanations, such purpose is legitimate and warrants the court, in the exercise of its discretion, in permitting the use thereof in evidence. That situation exists where it is necessary for a non-expert to understand the complicated structure of the human anatomy and the existence in the human body of foreign substances, or of any abnormal condition. That has been several times recognized by courts since the discovery of the *x*-ray process of laying the human frame bare to the eye and transferring the appearance thereof by the photographer's art, as in ordinary cases of photographing objects. It is the duty of courts to use every means of discovering the truth reasonably calculated to aid in that regard. In the performance of that duty, every new discovery, when it shall have passed beyond the experimental stage, must necessarily be treated as a new aid in the administration of justice in the field covered by it. In that view courts have shown no hesitation, in proper cases, in availing themselves of the art of photography by the *x*-ray process.

AMERICAN.

1. **Diagnosis of Gallstone.**—Stockton reports a number of cases showing the difficulties in diagnosis and calls attention to the fact that cholecystitis is often mistaken for gastralgia. We must remember the curious signs of transient pyloric obstruction that follow adhesions of the liver and gall-bladder, and the lower end of the stomach, and that jaundice is far from a necessary accompaniment of cholelithiasis. It may offer important evidence as to the location of the stone, but when present, is often the result of angiocholitis and, when intermittent, probably depends on the presence of a stone in the terminus of the cystic duct, or of a stone free in the choledochus. When a steadily-increasing and persistent jaundice is met, it is safe to attribute the cause to outside pressure, exercised on the common duct by growth in the head of the pancreas and elsewhere, and not by stone in the biliary ducts. Osler's rules for differentiating between jaundice from gallstones and that produced by a growing tumor are sound, but we must remember that stone may be thus situated without the presence of the phenomena. If asked to name the chief symptoms of gallstone disease Stockton would say that these are: 1. Paroxysmal pain; 2, tenderness below the junction of the ninth rib and cartilage; 3, vomiting; 4, ague-like fever; 5, jaundice; 6, the formation of tumor; 7, collapse; 8, the passage of calculi in the stools.

2. **Hernia.**—The following points are laid down by Ochsner as essential for permanency of cure: 1. The wound must heal primarily so that there be no cicatricial tissue as a point of weakness. 2. The stitches must not be drawn tightly so as to produce pressure necrosis. During the healing of every wound there is a certain amount of edema for the first few days and if the stitches are drawn very tightly, pressure necrosis will be produced and cicatricial tissue, which is always weakening, will follow. It is best to just have the stitches drawn tightly enough to bring the surfaces barely in apposition. 3. The edges of the surface to be united must be free from fat and other unstable tissue. 4. The tissues should be manipulated with the greatest care during the operation, so as not to injure them. 5. The wound should be supported by broad rubber adhesive plaster strips which aid materially in securing a desirable condition of rest. 6. The patient should be kept in bed for two or three weeks so as to give the wound an abundance of time to become firm. 7. After the operation, abnormal intra-abdominal pressure should be eliminated. We should protect against constipation and obstruction to urinary passage, and meet the condition of obesity by proper systematic dieting and exercise. Considering the four chief forms of hernia separately, he says: I. In inguinal hernia it is specially important to secure subsequent union throughout between Poupart's ligament on the one side and the tissues of the internal oblique and transversalis muscles on the other. In the upper portion of these tissues the defect occurs in cases of recurrences. 1. In order to secure this condition, the portion of the sac contained in the inguinal canal must be removed well up into the peritoneal cavity, so that no portion of it can be interposed between the layers. In ordinary cases the entire sac should be removed; in congenital hernia the lower portion of the sac may be left to make a tunica vaginalis. In very large hernias with thick adherent sacs, it is well simply to resect the portion in the inguinal canal, making sure that none will be interposed between the layers. 2. For the same reason it is important to dissect away all portions of fat, loose connective tissue and muscle that might become interposed, special care being taken to expose the ledge formed by Poupart's ligament. It is well to resect any portion that reaches beyond the internal abdominal ring. II. In femoral hernia the opening through which the sac protrudes is a perfect ring, consequently, it is not necessary to do anything beyond dissecting out the entire sac well up into the peritoneal cavity, permitting the stump to retract so as to leave the ring perfectly free. It is better not to meddle with the ring as all the methods devised for closing have a percentage of recurrences. III. Ventral hernia following laparotomy. Here permanency of results depends on the care with which all the anatomic layers are dissected out and the corresponding ones united. He has found it most satisfactory to insert silkworm-gut sutures down to, but not through, the peritoneum, from three-fourths to one inch apart and to leave these untied until the layers have been united separately with chromicized catgut sutures and then to tie the silkworm-gut sutures over all, being especially careful not to tie them too tightly. IV. Umbilical hernia. Mayo's method is recommended, which consists in overlapping of the edges of the hernial ring, preferably from above downward, from one and one-half to two inches, after removing the hernial sac and disposing of its contents according to the conditions found. It is necessary to dissect back the fat so that the strong connective tissue of the two layers may become strongly adherent. Usually the upper edge of the ring is slipped beneath the lower one at a distance of one and one-half to two inches and sutured in place with from three to five chromicized catgut stitches, then the lower edge of the ring is drawn upward and sutured in place. It is remarkable how firm a closure this method will accomplish. Ochsner has used it so far in 11 cases with success.

3. **The Neurasthenic Spine.**—Lovett's paper reviews the painful affections of the spine in which the subjective symp-

toms are out of proportion to the objective signs, and where organic disease can not be found. While the range of severity is great, the type is pretty uniform. He groups them into four classes: 1. Irritation of the spine due to faulty attitude. 2. Those due to severe traumatism. 3. Those due to slight traumatism. 4. Spinal invalidism, understanding by this the neurasthenic conditions which appear to be more an impression of a general disturbance of nervous function than a local affection. The treatment of the groups is given as follows: 1. By correcting the faulty position, treating the muscles, stimulating local circulation, etc. 2. In cases due to severe injury, recumbency and support are required in addition to orthopedic methods. Fixation of the spine is the first requirement. 3. In cases due to slight injury, while supporting apparatus may be of value, massage, douches and hot air are most likely to be of use, with exercise later in the case. 4. The local measures for spinal invalidism are much the same as those submitted above; but the principal thing is to build up the patient and the case comes properly under the care of the neurologist. The essential of treatment seems to consist in the progressively increasing use of the spine under proper conditions without too much regard to the subjective symptoms.

4. **Rheumatism and Rheumatoid Simulants.**—Walsh discusses the different types of rheumatism, or what is called rheumatism, such as gonorrheal and septic arthritis and acute rheumatoid arthritis which must be considered as of microbic origin, toxemic arthropathies, and arthritic neuroses. Here he calls attention to the effect of flat-foot in producing symptoms of rheumatism in the calf of the leg and in the toes, also joint injuries which are apt to be aggravated more or less at times with changes of the weather. These cases are not rheumatism, but are due to the interference with the lymph paths and premature senility of the parts. Occupation neuroses such as brachialgia are noticed, in those engaged in telegraphy, typewriting, etc., the effect on the leg by the use of treadles, the motorman's arm, baseball-players' "glass arm," etc.

7. **Sacro-Iliac Tuberculosis.**—Thienhaus describes the condition of tuberculosis of the sacro-iliac joint, showing the way in which abscesses may point and the complications to which they may lead, and the difficulties in diagnosis, etc., that may occur. The treatment he thinks advisable is rest to the part if it can be applied in the early stages. Schedes' or Delbet's radical methods are also considered, with their advantages and disadvantages.

10. **Bottini Operation.**—Horwitz concludes his article in this number, giving a lengthy table of the experiences of 50 operators covering several hundred operations. From the results obtained from the list of cases tabulated he draws the following conclusions: "1. There is less fear on the part of the patient to submit to the operation than there is to any other surgical procedure so far suggested for the relief of prostatic hypertrophy. 2. The principal advantages to be derived from the method of treatment are: A short time only is required to perform the operation, which is attended with little shock and usually slight loss of blood, convalescence is rapid, and the mortality is lower than that by any other radical measure. 3. Cures result in the large majority of cases, especially if the operation is undertaken early. Marked improvement may be looked for in a vast number of cases, where otherwise individuals would be condemned to suffer, as the danger attending any of the other radical methods of treatment would be too great to warrant their employment. 4. Failures occur in but a comparatively small percentage of cases, want of success being due to the pathological changes and complications which have taken place. Especially is this true in those instances where an incurable cystitis exists. 5. The operation is contraindicated when a valve-like formation exists, or where there is a greatly increased overgrowth of the three lobes, associated with tumor formation, giving rise to a pouch, above and below the neck of the bladder. 6. It may be employed with benefit, and safety, as a palliative measure in cases of prostatic hypertrophy of long standing, associated with cystitis, when the general health will be improved and constipation, which is usually associated with this condition, relieved, mitigating the prostatic spasm of the urethra, and rendering the insertion of the catheter easy and painless. 7. Pyelitis, when present, adds greatly to the danger of the operation, but is not always a contraindication to its employment. 8. The character of the growth has but little bearing on the result of the operation. 9. The operation may be employed as a safe and satisfactory means of causing a suprapubic fistula to close, which so frequently follows a suprapubic cystotomy when the prostate gland is hypertrophied. 10. In suitable cases it is not only the best radical measure thus far devised for the relief of prostatic hypertrophy, but is attended by the smallest mortality. 11. The operation is especially indicated in the beginning of obstructive symptoms due to hypertrophy of the prostate gland and may be regarded as a prophylactic method of treatment. 12. The operation is capable of producing a symptomatic cure in a great number of cases of various conditions and configurations of the prostate gland due to hypertrophy, as is shown by the disappearance of prostatic spasm, the restoration of the function of the bladder to its normal condition, and the improvement of general health. 13. When operating early, before the prostate has become much enlarged, the safest method to pursue is to perform a preliminary perineal cystotomy, introducing the 'perineal galvano-cautery incisor' of Chetwood, so as to make the incision in the prostate. 14. In some instances a prolonged preparatory treatment is necessary before the operation can be safely undertaken. 15. In cases of prostatic obstruction, which have existed for a lengthened period, where there is chronic cystitis, the physical condition of the patient being below par, both local and constitutional treatment must be persisted in for months after the operation before the great benefit derived from the procedure can be insured, which treatment would be ineffectual unless the obstruction had first been removed."

11. **Arterial Degeneration.**—The popular notion of the chief danger of arterial degeneration is that of the rupture of the blood-vessel. This is incorrect, according to Bishop, as such accidents rarely do damage excepting in the brain. The danger of establishment of secondary heart disease and kidneys, or the interference with brain circulation, producing thrombosis, is far more to be dreaded. It is the disease that belongs to the most useful, active members of the community. Most such cases, if early recognized, are found in successful young men who work under mental tension and combine their work with a certain amount of dissipation. The management must consist more in hygienic measures than in drugs. Syphilis is more often the cause than is likely to be believed, and here, on account of the general good effect on high arterial tension, the iodids will be found useful. Alcohol should be limited or suppressed. Digitalis is important and iron as in anemia, but in the early stages either of these may not be so useful. If any chronic intoxication exists the cause must be removed. An especial type is mentioned of neurasthenia in persons who have been living a strenuous life and carrying undue responsibility. The bromids here are of the greatest value. The influence of arterial degeneration on the organs of special sense is mentioned. The rupture of a small blood-vessel into the eye in a person past middle life who is suffering from the strain of overwork is a sign that should not be neglected. The importance of attention to early diagnosis in these cases is shown by the fact that change of mode of life, and proper treatment will in many cases bring about an arrest of the conditions.

16. **Rheumatoid Arthritis.**—The confusion of this condition with osteo-arthritis is dwelt upon by Painter, who points out the differences and illustrates them by skiagraphs. He discusses the various forms, and especially Bannatyne's theory as to its bacterial origin, but thinks that this is not proven, for the following reasons: "1. Failure to satisfactorily demonstrate the organism itself, and the equally significant fact that the lesions found in the joint tissues are not such as are produced by any bacterial cause. 2. That the 'chronic' stage in the disease does not present lesions, either gross or histological, which are at all derivative from the 'acute' stage, and that therefore we

must exclude from rheumatoid classifications any disease with hypertrophic bone lesions. 3. It is suggested, though not proven, that the changes in rheumatoid may be due to faulty metabolism, the absorption from the digestive tract of toxins, or some chemical product of intestinal digestion, which ought not to be thus absorbed, if all tissues were properly performing their functions."

18. **Courvoisier's Law.**—Courvoisier's law is that when the common duct is obstructed by stone, dilatation of the gall-bladder is rare, but when obstructed by other causes, this condition is common. This was announced in 1890 and confirmed by Mayo Robson two years later. It appears, according to Cabot, to be pretty fairly established by statistics, but has, as yet, not been generally noticed in American medical literature and he calls attention to this fact. The explanation of the non-dilatation of the gall-bladder with stone in the common duct is considered by Courvoisier to be due to thickening of the bladder from chronic inflammation, which tends to the formation of stone, involving the common duct. It is, in the great majority of cases, contracted or atrophied and incapable of distension. This is possible, on the other hand, when the common duct is blocked by cancer of the pancreas or other outside causes; the walls of the bladder are then thin and easily distensible, so that the backing up of bile behind the obstruction readily distends them. The facts are explainable also by Fenger's theory of the ball-valve action of stone in the common duct, which releases the bile and thus prevents distension. The value of the law is in the diagnosis of cases of chronic jaundice with or without enlargement, and if Courvoisier's law will enable us in these cases to distinguish curable from incurable, operable from non-operable, lithogenous from non-lithogenous cases, its importance is obvious. Cabot thinks that it can be relied upon to an extent rarely possible in a matter so uncertain as physical diagnosis.

20. **Craig Colony.**—Jelliffe gives his impressions from a three months' visit at Craig Colony, showing how the isolation of epileptics in settlements by themselves has improved them. The elimination of all excitement and notice as to their attacks has an effect in the diminution of their frequency. Good food, open air, labor and sociability are also important factors. The patients there received their first chance to learn to work, and though they can not do full workmen's tasks they learn to be of some use in the world. The tact and judgment of the attendants go a long way. Quiet and steady work and pleasant surroundings seem to have a direct effect on the frequency of the fits. The advantages to medical science of the institution are noticed and he thinks that it is the greatest opportunity any country has ever had for studying the disease in its hereditary, causative and therapeutic aspects. It makes life bearable for most of its inmates, and some it strengthens and cures. He hardly knows which to admire most—the breadth of mind that evolved Craig Colony, or the conscientious, wise and energetic administration of its affairs.

23. **Quack Advertisements.**—Stuver reviews the various evils of quack advertisements as they appear to him, and offers his summary in the following: 1. The great life-saving discoveries have been made by quiet, unobtrusive men. 2. Quacks and charlatans have never made any great discoveries in sanitary science, but, on the other hand, have always opposed scientific progress and investigation. 3. Quackery flourishes best in an atmosphere of ignorance, credulity, and pseudo-science, and is promulgated by boastful, arrogant pretensions, and public advertising. 4. Antivaccinationists, antivivisectionists, christian scientists, *et id omne genus*, by opposing preventive sanitary measures and scientific investigations, facilitate the spread of contagious and infectious diseases, oppose the stamping out of diseases already established and impede investigations as to the causation, prophylaxis and cure of disease. 5. The newspapers, which derive a large part of their revenue from advertising, nearly always espouse the cause of the so-called commercial interests, regardless of the fact whether they are supported by truth and justice, or are opposed to the best interests of the public. This is well illustrated by the recent occurrence of bubonic plague in San Francisco. 6. The boastful pretensions and misrepresentations of quack advertisements (patent medicines) lower the public regard for truth and fair dealing and encourage falsehood and duplicity. 7. The bold and shameless introduction of advertisements, calling attention to and suggesting vile, immoral and even criminal acts, debases and demoralizes the young, and leads to disease, crime and degeneration."

24. **Vaginal Cancer.**—According to Williams, from an analysis of the statistics, this form, though the most common of all primary vaginal neoplasms, furnishes less than 1 per cent. of all cancers. It is difficult to explain its origin by any theory of irritation, and he reviews the development and anatomy of the organs and mentions especially certain small bodies which were discovered by Davidsohn and are considered as aberrant offsets of cervical glands. He suggests that foreign elements of this kind furnish the germs, whence cylinder-celled glandular cancers of the vagina arise, and Wolffian and Müllerian "nests," which are of common occurrence, may also play a part. There are two varieties of this cancer mentioned: 1. Where the new formation does not progress much beyond the initial stage and the ingrowing cells preserve their normal form and their mutual relations are but little altered, the columns fail to penetrate deeply and the malady progresses slowly, and dissemination is exceptional. This is the tubular variety. With the more common type, the lobular form, the changes are more rapid, as other parts are secondarily affected. Several instances of vaginal cancer developing from hyperplastic lesions, leucoplasia, ichthyosis, etc., have been reported. In a few cases kraurosis has been known to have a similar termination. The symptoms and characteristics are pointed out and it is remarked that, as in cancer of the uterus, the dissemination of the disease in the internal organs and distant parts is not very common. The disease appears usually in the adult in post-meridian life, but in many cases it occurs at an earlier age than is common with cancer in general. In 76 cases Williams found it began between 20 and 30 years in 12, and it has been reported at a very early age, but such cases are to be looked upon with suspicion. The average age of onset is only 40 years, while that of the onset of mammary and uterine cancer is found to be 44 and 48 years respectively. Nulliparæ are as prone to the disease as multiparæ, and the mean fertility does not seem to have been affected, the average of births being a little above the usual. In diagnosis it should be remembered that secondary cancer of this part is much more common than primary and neighboring organs from which the disease has originated must be looked for. The microscope must distinguish between the sarcomatoid growths ,and septically infected and sloughing myomatous tumors are to be generally determined by careful digital examination. Other disorders which may cause trouble in diagnosis are syphilis, tuberculosis, and chronic inflammatory affections, and he has seen one case of vaginitis verrucosa mistaken for cancer. The surgical treatment is an open question. In most cases of active or rapid and insidious progress this is impracticable with any prospect of advantage, and even the most favorable cases are apt to be disappointing as regards results. Pregnancy does not seem to be affected by the existence of vaginal cancer, though it affects, of course, the chances for the mother's and the child's life. The only surgical intervention likely to be required would be for the conservation of a viable fetus. Cesarean section is the operation usually indicated and its results are favorable as regards the child, though the maternal mortality is likely to be considerable.

26. **Typhoid Bacilli in the Blood.**—Hewlett reports twenty-four cases of examinations, and says that to attempt generalizations from these would not be justifiable, but nevertheless suggests that, in the great majority of cases of typhoid fever, there is an infection of the blood by the bacilli during the early attack of the disease. This is not, however, properly a septicemia, for the number of bacilli present is ordinarily very small. During the third week of the disease, or when the temperature begins to fall, bacilli are no longer to be obtained

in blood cultures, but appear again at the onset of relapse and disappear with its disappearance.

27. **Obstruction of the Bladder.**—Bird's method consists in doing away with the catheter and using a bulb syringe in connection with a fountain syringe. The use of gentle, slowly increased, and regulated pressure will cause the liquid to enter the bladder and the rest is easy. The bulb and discharge tube of a bulb syringe are connected to the tube of a fountain syringe; a hard nozzle guarded by a soft-rubber tip supplants the catheter. He thinks the advantages of the method are that there is greater safety from infection, less pain and nervous reaction and that better results are obtained by the use of the bulb syringe in connection with the fountain syringe.

28. **Tuberculosis in Children.**—Knopf reviews the causation, prognosis and treatment of tuberculosis in children. He finds but little evidence of direct heredity and holds that the majority of cases are infected from without and not from within. The frequency of tuberculosis in childhood is noticed, the dangers of expectoration in the neighborhood of children and also the fondling and kissing by tuberculous parents. The ideal way to solve the question of transmission of parental tuberculosis would be separation, but this is impracticable. He dwells on the hygiene of children's nurseries and playgrounds, objects to their visiting menageries and speaks of the importance of school inspection, separation of tuberculous children from other children in schools, the restriction of reproduction by tuberculous parents, necessity of cleanliness, exercise, hydrotherapy, etc., and the prevention of child labor.

29. **Blood in Infancy.**—The three specific characteristic factors of blood in infancy are first noticed by Light: 1. The blood of infants tends constantly to embryonic characteristics when the clinical balance is disturbed. 2. Such disturbances produce blood changes out of proportion to the exciting cause, as measured by the adult standard. 3. Lymphocytosis is pronounced; the spleen tends to enlargement and splenomegaly has not the signification in childhood that it has in adult life. The presence of nucleated red corpuscles also has not the grave significance that it has in later life, but karyokinesis in the circulating red cells is rare and of serious import. The leucocytic count is higher in the early years. The exact age at which lymphemia ceases is not known. Polymorphonuclear elements, according to Engel, average 60 per cent. in normal children of the tenth year. From 2 to 10 per cent. of eosinophilia is probably normal in early years and an increase in acid-staining cells has not the same signification in early life. The clinical determination of abnormal states in infancy must proceed, therefore, with the ill-balance of the normal type in mind. The development of children must be taken into consideration. The different types of blood changes found in diseases like gastro-intestinal disorders, typhoid, pneumonia, tuberculosis, scarlet fever, etc., are remarked on. Leukemia seems to have been rare according to the New York statistics, but a number of cases have been reported from other localities. The existence of von Jaksch's anemia seems to be questioned by the author.

32. **Cholecystectomy.**—The various deductions in regard to cholecystectomy for cholecystitis and cholelithiasis are summed up by Gibson as follows: "In properly selected cases it is an extremely simple and safe operation. It is a curative operation, doing away with subsequent attacks of cholecystitis, and, more remotely, of renewed stone formation. It eliminates the disagreeable possibilities of long-continued biliary and mucous fistulæ. It is indicated in certain technical conditions, such as atrophic or (for drainage) inaccessible bladder, obliteration of the cystic duct, or impacted stone in the cystic duct, and in hemorrhagic conditions of the gall-bladder. It is a prophylactic measure against the development of carcinoma on the site of long-standing irritation. It offers the prospect of a shorter and easier wound-healing and convalescence. It is not to be employed indiscriminately, but has its proper limitations and contra-indications."

36. **Neuralgia of the Rectum.**—The conditions of neuralgic pain in the rectum are numerous. Monroe holds that we can not have simple neuralgia there without some causal pathologic condition. Coccygodynia, which is of the same nature, is included in his consideration of the subject, and he is inclined to think that it is always due to some local cause and that it is not purely hysterical. The treatment of rectal neuralgia, of course, must depend on the local disease if it can be found, whether it be fissure, ulcer, fistula, enlarged prostate, uterine or ovarian disorder or floating kidney. Constipation must be attended to. He has seen two cases cured by dilating urethral strictures. He usually gives the patient once in ten days 10 gr. of calomel in grain doses every two hours and follows this with one or two teaspoonfuls of phosphate of soda dissolved in a full glass of hot water and then after this gives 30 gr. of sulphate of quinin in 5 gr. doses four or five hours apart, using an enema of a quart of warm water twice a day, to which a teaspoonful of Merrell's liquid hydrastis or Pond's extract has been added. The sacral and coccygeal regions are also painted with tincture of iodin once a day. He has obtained good results from sulphate of strychnin, 1/40 gr. three times a day, combined with five drops of Fowler's solution. These patients are frequently debilitated and need to be built up, and he has followed the practice of divulsing the sphincter in nearly all cases so that no overlooked fissure can escape. In conclusion, he cautions the physician to question and look for specific disease and to investigate closely until absolutely certain that the condition does not exist.

38. **Railway Surgery.**—Cottam reviews the statistics of railway injury, showing how the aggregate number of casualties has increased with increased business and mileage, and the consequent growth of railway surgery. He alludes particularly to the civil malpractice question, the misuse of legal remedies and suggests medical insurance against blackmailing suits, calling attention to what has already been done in Minnesota in this regard. Were reputable practitioners admitted to associations paying a fixed membership fee and assessments to meet the requirements, the blackmailer or false claimant would be less likely to try to meet a united profession than a single individual against whom he thinks he may succeed.

43. **Hemorrhoids.**—The method for suturing hemorrhoids claimed as original by Mann and which he considers avoids the possibility of hemorrhage, guards against stricture, and shortens the period of convalescence, is described by him as follows: Clamp the hemorrhoid in the usual way, and with scissors cut it off just above the clamp. Wipe the surface clean. Now, with a catgut suture, begin at the top and pass the needle through the base just beneath the clamp and tie it. This holds the top secure. The needle is then passed through at a distance of one suture hole lower down, then it is turned and passed back through the first suture hole, or near it, and pulled tight. It is now carried by the second suture hole to the distance of one more and thrust through. Then it is turned and passed back through the second suture hole, pulled tight, then carried by the third suture hole to the distance of another and returned at the third and so on. Each turn is pulled tight as it is taken. All the threads pass beneath the clamp, and every part of the stump is held tight by a loop of the suture. Hemorrhage now seems impossible. Stricture is avoided by leaving sufficient mucous membrane between the hemorrhoidal masses removed. Three masses are as many as it is usually necessary to remove, and it is practically never necessary to remove more than four. If one does not wish to use a continuous suture, but tie as he goes along, the interrupted suture may be inserted beneath the clamp. No space should be left between the sutures because of possible hemorrhage from vessels not controlled by the sutures. To insure closure of the raw surface for healing by first intention, a second suture is tied once beneath the clamp at the top, the clamp is removed and the suture is brought down as a continuous over-and-over suture. The healing is by first intention and only a few instruments are required; the ordinary pedicle clamp, and a short round moderately-curved needle will ordinarily suffice. The superficial suture should last in position

about 7 to 9 days; the deep suture may be more quickly absorbed. If the superficial suture absorbs too quickly, there may be a slight surface left to be covered over with epithelium later.

46. **Diphtheria.**—A peculiar epidemic of diphtheria in Montclair, N. J., has been traced to a dairy where one or two milkers had suffered from a slight inflammation of the throat not sufficient to be diagnosed as specific diphtheria. A bacteriologic examination, however, showed diphtheria bacilli in the exudate. Other cases ceased to appear after the dairy was closed. The men had become infected by taking milk bottles away from an infected house and had themselves infected the milk probably through their respiration. The cases all occurred on this one dairy route and some curious associations of the milk with the existence of the disease are noted. One patient confessed to drinking milk habitually and liked the top of the bottle early in the morning, while another person closely associated with her never uses milk. The milk drinker had the disease.

47. **Diphtheria.**—Newton reviews the same epidemic, calls attention to the importance of the human breath as a source of infection and thinks that this has not been given sufficient attention by the profession as the cause of this disease.

53-63. **Appendicitis.**—The opinions of various prominent physicians on this subject are collated by the editor. A number of questions were propounded. As regards mild or moderately severe attacks, Wyeth, Roswell Park, Stockton, DeForrest Willard, Edwin Martin, Turck and Maurice Richardson would rely on emptying the bowels and quiet unless symptoms become more severe. Park would err on the side of operation rather than otherwise. Morris, Ochsner and Murphy would operate early. In severe cases, in the early stages, nearly everyone would operate. Ochsner would in some instances act as in the former case if no safe surgeon was at hand. DeForest Willard would operate as soon as the diagnosis is reasonably certain. Turck would wait for perfectly clear diagnosis before operating. During the active stage of a moderate attack most would watch the condition to be ready for operation. Dr. Morris would operate anyhow. Ochsner would use exclusively rectal feeding, no nourishment or cathartics by the mouth. In very severe attacks during the active stage operation is the rule, though Ochsner would consider the same treatment as before. Of course, if the patient has collapsed, stimulants will always be required or possibly operation might be impracticable. When the case is subsiding after expectant treatment and there is a brawny, tender swelling over the cecum, Wyeth, Park, Ochsner, Murphy, Stockton, Willard, Martin and Turck would wait. Morris would operate, as also would Richardson if the patient is not in a favorable condition for waiting. The only case in which Park would advise against operation is where the patient is moribund and the case hopeless. Morris would do so if a competent surgical operator is not at hand. Ochsner would advise against operation where the infection has extended beyond the appendix and has not produced definite circumscribed abscesses. Murphy would operate in any case where the serious condition of the patient did not forbid it. Stockton and Martin and Richardson rather agree with Murphy and Park. Wyeth is conservative. He would let the patient alone if the acute symptoms subside in a mild attack. Most would operate during the interval between the first and second attacks. Some would prefer to wait until the third or fourth attack and would operate when convalescence seems to be complete.

71.—See abstract in The Journal of September 14, p. 713

75. **Stypticin.**—Boldt finds that this substance (cotarnin hydrochlorate), which is derived from narcotin, one of the alkaloids of opium, is specially useful in certain forms of uterine hemorrhage. His former experience was published in the *Medical News* of April 8, 1899, and since that time he has tried it on a number of additional patients under various conditions, such as profuse menstruation in virgins, bleeding after full-term delivery with pelvic inflammation and in atypical bleeding after confinement caused by retention of the decidua, also during the climateric period when no pathologic condition can be found. Where it is caused by inflammation of the uterine mucosa either alone or with chronic neoplasms this drug, like all others, fails, and this statement holds good when retroflexion or version accompanies the endometritis. It is also useless in endometritis fungosa, though it is of benefit in some cases of simple endometritis. In one case of irregular uterine hemorrhage of unknown cause he had a satisfactory result follow the use of the drug. He has also found it useful in bleeding caused by para- or peri-metritic exudates and better in this respect than other remedies. In typical bleeding associated with subinvolution it is of great value and in a few instances bleeding during pregnancy has been controlled without any uterine contraction having been caused. He has not found it especially valuable in controlling hemorrhage from fibromyomatous tumors or from malignant growths. If quick action of the drug is desired it is best to give it in 2 or 3 grain doses in sterile water injected with antiseptic precautions into the buttock and repeated after four or six hours. Two or three injections should suffice, after which the remedy can be given by the mouth in capsules or tablets. He has given injections as high as 5 gr. without any bad results.

77. **Thiocol and Dionin.**—Thiocol (guaiacol-sulphonate of potassium) has been used by Johnston in various bronchial disorders with great success, but he has found it of no special use in cough arising from pathologic conditions of the pharynx, nasopharynx or tonsils. He gives large doses, 45 grains, three times a day. In typhoid fever he finds it an ideal intestinal antiseptic tending also to diminish bronchial complications. It may be prescribed in cinnamon water or pancreatic essence 5 grains to each fluid dram. Dose, one teaspoonful three times a day, two or three hours after meals if it is intended to act on the intestinal mucous membrane. This will be about 7.5 grains to the dose and it is sufficient in these cases. Dionin (ethyl-morphin hydrochlorate) must be placed as an intermediate between morphin and codein in therapeutic power. Johnston finds it efficient as an analgesic in gynecologic cases in .25 grain dose, but in severe conditions involving pain, morphin is superior. Dionin does not constipate and has none of the co-existing by-effects of morphin and is preferable to morphin, codein or heroin for use in expectorant mixtures in his opinion. He mentions a case of severe delirium in pneumonia which was controlled completely by this drug. He dissolves 2 to 4 grains in 2 ounces of essence of pepsin, and gives it in teaspoonful doses.

81. **Trachoma.**—The dangers of trachoma are especially mentioned by Wilder, who gives a map showing its prevalence in the different parts of the state of Illinois, where its distribution appears to be very unequal, as it prevails mostly in the southern and central portions. There is a marked increase noticeable of late years in the reception of cases in the Illinois Eye and Ear Infirmary from different parts of the state. He thinks it is the duty of the medical profession to endeavor to educate the community on the subject and to prevent the spread of the disease through ignorance, which seems to be the main cause.

86. **Coal-Tar Antipyretics in Children.**—McGee thinks that for fever in children, small doses of aconite or phenacetin are of use. Phenacetin he thinks the safest coal-tar preparation, though he has also found kryofin efficient and safe. In whooping cough he prefers quinin; in influenza he finds small doses of phenacetin as efficient as in the adult.

87. **Appendicitis.**—Wise argues for conservatism in appendicitis and believes in the use of opium in these cases. He holds that the tolerance in each individual case should be estimated and the dosage regulated accordingly. When called early to see a patient, a saline cathartic should be advised and opium should be deferred until the bowels are evacuated.

90. **Perineal Prostatectomy.**—Goodfellow considers his technique in this operation original. He operates with the patient in an exaggerated Simon position, enters the mem-

branous urethra and bladder on a lithotomy staff, and by using pressure above the pubic bone, forces the viscus downward, and then enucleates the prostate. The after-treatment is simple, consisting of daily irrigations of the bladder with passage of good-sized sounds for ten days or two weeks where the condition of the bladder demands it. In uncomplicated cases a part of the urine will be passed in the natural way in forty-eight hours, and no further treatment is called for other than the introduction of sounds until all danger from contraction is over. If a single incision is found insufficient to remove the gland, the high incision can easily be made, and the prostate extracted by the combined method. He thinks in cases where there is acute suppurative cystitis, a perineal opening is necessary even in high cystotomies, and that suprapubic drainage alone is dangerous.

106. **Appendicitis.**—Grothan believes in a rather conservative practice. In catarrhal appendicitis—that is in the great majority of cases—he would not operate, but would rely upon opium and anatomic and physiologic rest of the parts. In suppurative appendicitis he would operate, but as a rule he waits for adhesions to shut off the peritoneal cavity. If temperature is high, pulse rapid, and vomiting persistent, it is better to err on the side of early operation. In acute perforating and fulminating appendicitis, operate as soon as the diagnosis is made, and see to it that the diagnosis is made early.

116. **Tremors.**—Solomonson's conclusions are as follows: "1. A direct question as to the presence of a tremor should be included in every examination blank. 2. The search for the existence of tremor should include at least: (*a*) The inspection of the outstretched fingers and hands. (*b*) The inspection of a few straight lines drawn by the applicant. (*c*) Some trials of the applicant's handwriting. (*d*) The inspection of the lips and of the tongue, as well during rest as when in motion, the extension of the tongue and the contraction of the lips. (*e*) The inspection of ocular movements. 3. In the description of a tremor, it should be mentioned whether it is rapid, moderate or slow, or at least whether it is vibratory or oscillatory. Then, whether present or absent during passive and active rest, in motion, or the tendency to motion, whether it stops or increases through one of these circumstances, and, finally, what parts of the limbs are affected." He describes in his article the various forms of tremor and gives tracings illustrative of the different types.

118. **Tropical Residence.**—The insurance companies should, according to Van Der Berg, as regards tropical residence, arrange applicants into three different categories: 1. Those who are about to move to warmer countries; 2, those who live in them; 3, those who have returned. The various diseases met with in the hot climates are noticed, the deductions having been drawn from experience with the Dutch colonies in Asia. He thinks the following conclusions may be deduced from his study: 1. The insurance of people returning from hot countries needs a special examination: (*a*) We must find out how the change of climate has been borne. (*b*) We must look for the symptoms of tropical diseases. 2. The insurance companies should entrust the examination of such people to physicians who have lived in the tropics, and preferably to those who are acquainted with the region they inhabited. In this matter especially, experience and practice are of the greatest usefulness. Often one may recognize at first sight whether the person to be examined has suffered from a disease of the liver, from chronic dysentery, from psilosis, beri-beri, or malaria. These first impressions must be controlled by a careful examination. Those who have seen few of these diseases do not possess this intuition, which seems to me to be of great importance. Nowadays physicians can everywhere be found who are competent to examine people entering into one of the three classes indicated at the beginning of the report.

119. **Ear Disease in Life Insurance.**—Burger, after a discussion of the various conditions and complications of ear disease, offers the following conclusions: "I. It is to the interest of life insurance companies to pay greater attention than has been done heretofore to the condition of the ears of applicants. II. In acute inflammations of the external and middle ears we must await the termination of the disease before granting insurance. III. In the same way, in some very severe cases of chronic external otitis the insurance should be postponed. IV. It is possible to admit without trouble the various forms of chronic catarrhal otitis. V. Chronic suppurative otitis media must always be declined if we observe the certainty or the probability of: 1. An inflammation of the attic or of the mastoid antrum. 2. A tubercular or cholesteatomatous affection. 3. A bony lesion. 4. A paralysis of the facial nerve, or 5, when otitis is accompanied with vertigo or cephalalgia or by considerable stenosis of the external duct. VI. Other cases of suppurative otitis media need not necessarily be declined. VII. As to the possibility of their being accepted with an increased premium, each case must be examined by a competent specialist and judged separately. VIII. When the suppuration has entirely ceased, there is no objection to acceptance. A permanent perforation of the tympanum alone constitutes an impairment of the risk. IX. Chronic suppurations healed by the radical cure may be accepted under an increased premium, notwithstanding the large bony losses, or the permanent retroauricular opening following the operation. X. Bilateral deafness is important, and severe cases of aural vertigo should require an increased premium. XI. It is highly desirable that the university teaching of otology, until now much neglected, should be improved and extended and that otological diagnosis should be required for the final examinations."

121. **Life Insurance Risks.**—Florschutz's article is chiefly in relation to tuberculosis and life insurance risks. He believes in predisposition and thinks that signs of it can sometimes be discovered. Underweight for the stature and age indicate a sickly tendency and insufficient nutrition, hence deficient resistance to disease.

126. **Gonorrhea.**—Dedman holds that gonorrhea is not usually treated on rational or scientific principles, but that its serious nature is overlooked, and that it is responsible for a considerable percentage of mortality reported. The patients are dismissed too early. He says the physician should impress the patient with the gravity of his disease and its pathologic possibilities, avoiding routine treatment and remembering that every case has its own pathologic peculiarities and must be treated individually. Let us employ every diagnostic means at our command to be thoroughly convinced that the patient is well before we dismiss him, remembering that it is these apparently cured cases that do more subsequent damage than all others combined, not only to the patient himself, but to his wife.

British Medical Journal, November 23.

Action of Iodids on the Heart and Circulation. RALPH STOCKMAN and FRANCIS J. CHARTERIS.—The authors have investigated the action of the iodids on the heart and blood vessels, which is of interest on account of their extensive use in aneurysm, arteriosclerosis and cardiovascular degenerative changes. Most authors attribute to the iodids a depressing action on the circulation, while a few deny this. Stockman and Charteris have made systematic observations on blood tension and pulse rate of numerous patients taking potassium or sodium iodids. The observations were made with the von Basch's sphygmomanometer and Gartner's tonometer, which detect and record slight changes in the arterial tension. The doses were usually 15 to 30 or 40 grains, a few patients, however, taking much more, up to 180, and one man suffering from spinal sclerosis took 300 grains per day. Some of the patients had healthy circulatory systems and were taking iodids for chronic rheumatism, sciatica, facial paralysis, etc. Others suffered from renal or cardiac disease, aneurysm, arterio-

sclerosis, bronchitis, etc. One patient suffered from severe iodinism, the others had it but slightly. Observations were taken regularly during the iodid administration, but in no case did any fall in the blood pressure occur or any change in the rate or rhythm of the heart. Even the man who suffered from severe iodinism maintained his arterial tension unimpaired, though he said he felt very depressed and ill. The depression seemed partly due to coryza and partly to the action on the nervous system. "The result of the observations is to show that potassium or sodium iodids, given to men by the mouth in therapeutical doses, do not modify the physical conditions of the circulation, and that therefore they neither directly weaken the heart nor dilate the arterioles. The therapeutic effects must be due to some other mode of action, and this is probably true also of some of the rarely occurring poisonous effects. It is sometimes observed, for instance, that iodids quicken and weaken the pulse, and this has been specially frequent in goiter; sometimes also their administration is followed by emaciation. There is good reason for believing that in neither case is this a direct effect, but is due to increased formation or alteration of the iodin-containing thyroid secretion, which has a powerful action on the circulation and on metabolism." The authors also have repeated and checked a considerable amount of experimental work on the action of iodid upon the circulation in animals. They notice a decided difference in the effect of iodid of potassium as administered by the veins, where its action as a cardiac depressant is very marked, while sodium iodid given in the same way produced very little, if any effect. A small, carefully guarded dose of the potassium salt caused a transient rise of blood pressure, with slowing of the pulse and increased size of the waves. When given by the stomach the depressing effect on the blood pressure is only observed after enormous doses, and is never very evident in man. It is an effect of potassium common to all potassium salts and seems to be due to the large amount of potassium salt striking the heart at once and in a certain concentration, for if the solution is very dilute and injected slowly so that it mixes well with the blood this effect does not appear. Although the blood pressure may sink to nothing, the heart muscles and nerve ganglia may not be killed, but may recover rapidly as the blood washes the poisonous salts out of the heart. Death may occur, however, from asphyxial convulsions brought on by overwhelming action. They have never seen the fall of blood pressure from dilatation of the arterioles mentioned by Sée and Lapicque. A number of experiments were also made on the hearts of frogs isolated, but they did not throw much light on the action of iodids on the heart and circulation of man and mammals. Iodids and iodin exert a very depressant effect on the muscles of the frog, no trace of which could be observed in mammals. They conclude, therefore, that sodium or potassium iodid, when given to man by the stomach in the ordinary dose, has no depressing effect on the action of the heart, blood pressure or arteries.

The Lancet, November 23.

The Etiology of Beri-Beri. Patrick Manson.—The importance of beri-beri is first considered, and Manson shows that it is not only endemic in the tropics, but has appeared in certain institutions on the British Isles, for instance the Richmond Asylum in Dublin. He also mentions a confusion in names, that is, other disorders have received this designation and it is possible that the term beri-beri covers more than one form of peripheral neuritis. There is a large and almost unworked field for the bacteriologist in the tropics. We should first, therefore, have a clear conception of the term we are discussing, and what he considers to be understood by the term beri-beri is a form of multiple peripheral neuritis occurring endemically and epidemically, characterized, as compared with other forms, by proneness to edema and to implication of the neuro-muscular system of the central organ of circulation; by complete absence of trophic skin lesions, of paresis of the muscles of the head and neck, of marked implication of the senses of sight, hearing, taste and smell and of the mental faculties. In common with alcoholism and arsenical neuritis there are locomotor disturbances, paresthesias, and hyperesthesias, with atrophy, and generally after the beginning, absence of patellar tendon reflex and of the superficial reflexes, the sphincters being intact. The patient complains principally of sweating, palpitations and breathlessness, weakness and numbness of the limbs, and swelling of the legs. Fever and diarrhea are far from being prominent features. The intensity and duration may be varied; either trifling and of only a week or two's duration, or may prove rapidly fatal, or last in varying degrees of intensity for months. Paresis may be the leading feature or muscular atrophy or anasarca, or there may be rapidly fatal paralysis of the right heart and diaphragm and respiratory muscles. It occurs generally in limited epidemics, in particular houses, etc., or it may spread over large areas only attacking limited foci therein. It occurs at sea on board ship, where it is apt to be rapidly fatal. The postmortem results are those ordinarily found in multiple peripheral neuritic degeneration of the peripheral nerves or ascending degeneration of the neuron and involving the corresponding intracranial cells. No immunity is conferred by an attack and the mortality ranges from 5 to 50 per cent. In some epidemics only a few are affected, in others almost everyone may be a victim. There are two theories of its causation: 1. The dietetic, which has been advocated by many writers, who generally attribute the disease to prolonged and uniform rice diet. The facts that support this are largely from Japanese experience, but epidemics elsewhere show exceptions. It has occurred in other countries with elaborate diet where there is no lack of nitrogenous food. In the prisoners of the Dutch colony of Java there seems to be some evidence that it follows the use of decorticated rather than non-decorticated rice. Another theory which Manson thinks more plausible is the germ theory, which is quite compatible with Japanese experience, and that the disorder has its origin in the toxin elaborated by a germ in the blood or tissues. In his opinion, the best supported theory by facts is that the diseases is purely an intoxication produced by toxins elaborated by germs whose nidus is located outside the human body, and he parallels it with alcoholism. The cause can be transplanted from place to place and therefore can not be of climatic or meteorological nature, and when so transplanted can multiply. This has been shown by numerous facts, by the transportation of Japanese to different localities where they have carried the disease with them, and it is not unknown on ships in the London docks. We can not, however, say what the toxin is, but its persistency in certain buildings and ships is certainly remarkable. The analogy with alcoholism is used by him largely in his reasoning. In conclusion, he enumerates several points that investigators in the etiology of beri-beri must be careful to attend to: "1. The diagnosis: they must avoid mistaking other forms of peripheral neuritis for that of beri-beri. 2. They must bear in mind the possibility that the disease may not have been contracted at the place in which it is declared. 3. That the toxin which produces an outbreak of beri-beri may have been imported as such and not manufactured, so to speak, locally. 4. They must carefully differentiate between predisposing or favoring conditions, such as overcrowding, heat and moisture, bad food, etc., and the actual direct cause. 5. Finally, they must recognize that the actual cause must correspond in its geographical distribution with the geographical distribution of the disease."

Twenty-five Years' Experience of Urinary Surgery in England. G. Buckston Browne.—In his second lecture Browne takes a more favorable view of the prospects of the prostatic patient than is commonly held. Why prostatic enlargement occurs, he says, can not be stated, but he would advise plain living, foot exercise, and very moderate sexual indulgence after 50 years of age as a prophylactic. He describes at length his method of conducting aseptic catheterization, and he maintains that there are no cases of prostatic disease where it is impossible to pass a catheter into the bladder. The India rubber catheter is the safest of any and will often work when all others fail. The worst cases are those where the distension has become chronic, and no surgeon should treat such as out-patients. Catheter life does not disqualify from

active life. He knows many instances of men active in the professions and even sailors and sportsmen who were in that condition. The complication of stone in the bladder is a serious one, and is mentioned at length. Browne puts little faith in castration or vasectomy. The only thing to do for a prostatic patient whose suffering can not be mitigated by the treatment is to open the bladder suprapubically in order to explore digitally for stone or tumor and at any rate to obtain rest for the organ. He emphasizes the importance of opening the bladder in such cases upon the point of a staff. When the prostate is large so that the organ often comes up well above the pubes, unless the staff is employed, it is possible to incise the prostate and not the distended bladder, and thus cause serious trouble. It is a curious fact, he says, how many cases turn out to be really cases of calculi hidden away in one of the many pouches to which such cases are subject. If a stone is found and the intravesical prostate is not very large it had better be left alone, but if it is large and there is no stone he thinks it would be good policy to attack the growth. He credits the operation entirely to McGill of Leeds, maintaining that Belfield's previous operation was practically an accident. The special points of technique are quoted from McGill. As for total extirpation by enucleation he considers the phraseology misleading. The prostate can no more be enucleated without the use of the knife than can a piece of the intestine. It is absolutely one with the urethra and bladder. This treatment has been used in error and by surgeons who have been fortunate in only meeting with the simpler or adenomatous form of prostatic enlargement where large masses are easily shelled out. He also maintains that he has shown that the bladder may recover its power fully even after long depending upon the catheter. Therefore, the operation is not contraindicated. He sums up his views, which were first expressed in 1893, as follows: "1. I believe that suprapubic prostatectomy should never be undertaken at the outset of catheter life unless regular auto-catheterism is difficult or well-nigh impossible. In cases of real difficulty I have seen several patients where vasectomy has been performed, and there has been no lessening whatever of the catheter difficulty. It must be understood that I believe that cases where regular catheterism is impracticable are very rare, and it is for these only that I would recommend suprapubic prostatectomy. 2. Prostatectomy should never be undertaken as long as the ordinary catheter life is a tolerable one. 3. If catheter life becomes intolerable, suprapubic cystotomy should be resorted to. By means of this proceeding the bladder can be thoroughly explored and any stone removed, which in these cases may easily have escaped detection by the more useful methods of examination. The prostatic growth can be fully examined and removed if the operator think it right to do so. If he deem removal inadvisable he can leave the patient with a suprapubic tube for permanent after-wear with the certainty that he will have materially improved the condition of the patient. Finally, should the operator decide to remove the prostatic obstruction there is a very good prospect, but not a certainty, of the power of natural micturition being restored to the patient. I would therefore strongly recommend all prostatic patients and their advisers to be content with the catheter life as long as it is tolerable, and in the vast majority of cases, with reasonable care, it will remain tolerable into extreme old age—until the end comes probably through other channels. I believe that, as Mr. Jonathan Hutchinson once said to me, 'good surgery may often be combined with bad practice.' The work of the world is not always done by those who are completely well. It is not wise for the elderly to run grave risks only on the chance of obtaining complete comfort. There is much truth in what Thomas Hardy says of one of his most fascinating heroines: 'In considering what she was not he overlooked what she was and forgot that the defective can be more than the entire.'"

A Note on Neisser's Test for Diphtheria Bacilli. L. Cobbett.—This author holds Neisser's method extremely valuable in distinguishing diphtheria from pseudo-diphtheria, but it is not infallible. It fails in a small proportion of cases to show the polar bodies of true diphtheria bacilli and shows minute or doubtful polar bodies in a few cases of Hofmann's bacillus. This fact, however, detracts very little from the value of the stain as a differential test because the exceptions to the general rule are so few. A good positive reaction is evidence that the bacilli are diphtheria bacilli; a definite negative reaction is valuable evidence but not alone conclusive, while a poor or doubtful reaction is not of much value either way. He describes his acetic acid modification of Neisser's stain, consisting in an application of a drop of 5 per cent. acetic acid to one edge of the cover slip and drawing the fluid under the glass by means of a small piece of filter paper placed on the other side. If the bacilli are watched while the acid is entering under the cover slip one sees first a current of fluid sweeping up loose bacilli and hurrying them away. A blue cloud next appears and blurs out everything for a second, then passes on, leaving the field bright and clear and the diphtheria bacilli showing the polar bodies as when stained as Neisser recommended, only the bodies are not brown, but blue. The Hofmann bacillus does not as easily decolorize as the diphtheria, and at the middle of each half a good deal of blue usually remains. With the diphtheria bacilli the stain is instantaneous and the picture revealed is not inferior to that of the Neisser specimen stain in the usual way. The method is so quick that it takes no appreciable time and can therefore be applied to every preparation having a micro-organism with the remotest resemblance to diphtheria.

Bulletin de l'Academie de Medecine, November 19.

Five Cases of Rupture of the Spleen in Malarial Subjects. Boinet.—The spontaneous rupture of the spleen during an attack of intermittent fever or pernicious malaria is possible. It is favored by the softening, the enormous enlargement of the organ, the congestion and the rapid increase in the body of the spleen which is liable to distend and burst the capsule. Sometimes the capsule is thin and normal in aspect, or it may be thickened and have lost its elasticity. Adhesions between the spleen, stomach and diaphragm drag on the organ or interfere with its movements, and thus favor rupture from slight traumatism. The alterations, hypertrophy and friability of the large spleens noted in chronic paludism were the predisposing causes in four of the cases related. In one the rupture occurred immediately after eating a hearty meal, with no external traumatism. Most of the ruptures were star-shaped, but in one case the spleen ruptured in a dozen places during an acute, comparatively recent malarial infection; no signs of traumatism could be discovered and an operation in time might have saved this patient.

Bulletin de la Soc. Med. des Hop. de Paris, November 14.

Methylene Blue in Treatment of Ulcero-Membranous Stomatitis. A. Siredey.—The affections of the throat caused by the spindle-shaped bacillus and spirillæ, have lingered for months in all the cases that have been reported. Siredey had occasion to treat a young man with this affection, the symptoms of a staphylo-palatine stomatitis predominating. He first painted the lesions with iodin, but found that they did not take the stain and the application had no effect. Remembering that these micro-organisms stain well with methylene blue, he treated the lesions by applying chemically pure methylene blue in powdered form on cotton wrapped on a stick, which he rubbed well on all the lesions. No inconveniences were observed except the blue stain of the saliva. The stomatitis was completely cured by the end of eight days; the blue had been applied six times.

November 21.

Serotherapy of Typhoid Fever. E. Chantemesse.—For many years Professor Chantemesse has been making a special study of this subject, and in 1892 he succeeded in producing an antityphoid serum which had a preventive action. It was not curative as it had no antitoxic action, and it was impossible to make an actual antitoxin until 1897, when he succeeded in isolating the true, soluble typhoid toxin, and at once began to apply it for the production of an effective serum for clinical use. He now reports the results of its application in 100

cases of severe typhoid fever. As the mortality in typhoid fever varies so much in different epidemics, he has collected the records of the cases at the same hospitals during the same periods treated by other methods. He found that the mortality of the 371 cases that were treated in nine Paris hospitals between January 1 and October 10, 1901, ranged from 12.28 to 56 per cent., and averaged 29 per cent. He found incidentally, that 404 cases of typhoid fever in children at a children's hospital terminated fatally in 10 per cent. In his 100 cases every patient treated before the tenth day recovered, and all the others except 6. Two of these did not receive this treatment until after the twenty-first day; one died of pneumonia and another from the consequences of a pre-existing extensive gangrenous eschar. These 100 patients treated with the serum were all in the nine hospitals mentioned except 10 in his private practice. They were all "gravement ou serieusement" affected. As a general rule, the injection was followed a few hours later by a slight febrile reaction as in case of antitoxin treatment of diphtheria. In twenty-four to thirty-six hours after the injection the general health shows marked improvement; the diarrhea is arrested, or at most, persists only two to four days after the injection. The influence on the pulse and blood pressure is most marked, and the slower radial pulse immediately after the injection, is one of the most constant and most significant signs of improvement. It usually accompanied the fall of the temperature. The condition of the pulse twenty-four hours after the injection indicates whether the disease is yielding slowly or rapidly and whether a second injection is required. Three injections were made in some cases, but usually one or at most two are ample. With the injection of serum, cold baths to reduce the temperature are needed only for a short time. The serum has an evident diuretic effect. The polyuria may reach 3 or 4 quarts a day, and it keeps up after the temperature has been normal for days, but the chlorids are scanty until recovery is well under way. When the kidneys were sound before the typhoid infection, the albuminuria induced by it vanishes after the injection. Chantemesse urges that the patients should be made to drink copiously, a glass of water or tea every hour at least, in some form. The blood changes after the injection and assumes the characters it presents during normal convalescence, returning gradually to normal. Complications were rarely observed. Perforation of the intestines occurred only in 3 cases, never in any patient injected before the ninth or tenth day. Otitis media was observed in 3 and slight phlebitis of the saphena in 2. Clinical experience therefore has fully confirmed the results of experimental research in respect to this serotherapy of typhoid fever. It has proved to be preventive, anti-infectious and antitoxic. He injects the serum at the elbow, as he thinks the venous network is so extensive at this point that the serum is more rapidly absorbed than from the skin of the abdomen. There were no after-effects except a very slight erythema was observed in 2 cases. When possible to apply the injection at an early stage of the disease, in vigorous adults, able to take cold baths, 10 to 12 c.c. of the serum was the average dose. The reaction is brief, and complete apyrexia may follow in seven or eight days. If there is still slight fever at this time, the injection is repeated, the dose ranging from 4 to 10 c.c. according to the height of the fever. In case the disease is only five days old, or the intoxication is extremely profound or of long duration, it is better to commence with 6 to 8 c.c., ready to recommence a few days later. When the reaction to the injection is very pronounced, he suspends all food and administers water alone. Milk and the juice of raw meat are peculiarly beneficial in typhoid fever. Strict care of the mouth is the most effective means of preventing complications on the part of the lungs. The cold bath should be used freely, and should not be omitted to reduce the febrile reaction after the injection. He urges the injection of the serum on a presumptive diagnosis without waiting for certainty. It can do no harm and may possibly ward off an impending attack as in diphtheria. But the resemblance ceases here. In diphtheria the serum suppresses or diminishes the intoxication and the microbes are dislodged from their haunts in the throat. In typhoid fever, on the other hand, the microbes are in the inaccessible internal organs. They can be dislodged only by phagocytosis. The immunization of the horses whose serum is effective, was commenced five years ago. The animals die if the vaccination is carried on too vigorously. The expenses of the long and costly researches were defrayed partly by the Pasteur Institute and partly by the municipal authorities of Paris. A number of temperature curves are reproduced. In some the temperature makes an even downward slope after the single injection. In all there was a constant drop of the temperature after the injection.

Echo Medical (Lille), November 17.

Cure of Lead Colic by Epidural Cocainization. Delearde.—The pains were immediately arrested in two cases of lead poisoning described by Delearde, after the epidural injection of 0.03 gram of cocain dissolved in 3 c.c. of water. With the abolition of the pains the characteristic obstinate constipation was relieved also. Each patient had an alvine discharge the same day, the first for a long time, in spite of repeated purgatives.

Journal de Med. de Paris, November 3.

Spontaneous Resorption of a Cataract. Trousseau.—A woman of 55 was operated on to relieve a severe attack of acute glaucoma. Iridectomy was done at the same sitting on both eyes, which had become affected in turn. A few months later a cataract began to develop in one eye, rendering it completely blind by the end of three months. Soon after this the cataract commenced to disappear, and in four months there was scarcely a trace of it left. Reuss reported a similar case last year; an elderly patient with glaucoma found that the cataract had been completely re-absorbed. He was able to collect 33 cases of spontaneous resorption of a cataract, and in more than half of them there was some complication—glaucoma in 7. Pathologic and especially glaucomatous eyes seem to be peculiarly favored with spontaneous disappearance of the cataract.

Presse Medicale (Paris), November 6.

Generalized Enterococcus Septicemia. J. Hulot.—The enterococcus should be considered as important a factor in pathology as the streptococcus and the pneumococcus. In a case of generalized septicemia induced by it, the symptoms developed in three weeks, commencing with gastro-intestinal phenomena, prostration and headache. The liver became painful and albumin appeared in the urine. Death occurred in dyspnea after defervescence. The liver presented the appearance of an old injury; possibly the enterococcus had determined lesions there before they had become generalized. The general affection was evidently the consequence of bad hygienic habits and the pressure of a corset.

Sodium Salicylate. A. Martinet.—Besides its influence in rheumatism and the uric diathesis, sodium salicylate is distinguished by its remarkable influence on the modification of the secretion of bile. It is the most active remedy at our disposal against insufficiency of the liver functions and is the cholagogue par excellence. Owing to its depressing action on the heart and brain, most marked with impermeability of the kidneys, it is contra-indicated in case of excessive susceptibility of the nerve centers, of organic affections of the heart and complete or relative impermeability of the kidneys. These contra-indications are not absolute in case the patient can be supervised two or three times a day.

November 9.

Treatment of Gastric Stasis by Dry Evacuation of the Stomach. Mathieu.—Occasionally the stomach may have to be irrigated, but usually aspiration of the contents is sufficient to relieve the symptoms which characterize Reichmann's disease. The empty stomach is thus evacuated by dry aspiration in the morning. Immediately afterward, 40 to 100 gm. of meat ground to a powder and stirred into a half or two-thirds of a liter of milk, are injected. This treatment has proved extremely successful except in cases complicated by

malignant disease. Mathieu's experience indicates that every case of stasis of the contents of the stomach or Reichmann's disease, which is not improved by this treatment, demands surgical intervention without delay.

Semaine Medicale (Paris), November 6.

Treatment of Diabetes Mellitus. R. LEPINE.—Diabetics can be classified as those with and those without diacetic acid in the urine. As long as there is no diacetic acid in the urine, the glycosuria may be diminished or disappear entirely on an appropriate diet and medication. In case of the presence of diacetic acid in the urine the glycosuria is a subordinate element and every effort should be made to banish this acid from the urine. If it persists in spite of this, the prognosis is almost invariably fatal. In treating diabetes it is well to commence by keeping the patient under observation for a few days in order to learn his habits of life. Whether glycosuria is due to a hyperglycemia or to an exaggerated permeability of the kidney, the ingestion of albuminoids must be restricted. Fats, like the proteids, may be a source of oxybutyric acid and its derivatives, diacetic acid and acetone. Lepine has one patient who excretes diacetic acid in increased amounts every time after ingestion of cream. Diaceturia may be diminished by an abundant carbohydrate diet, but this increases the glycosuria and is thus impracticable. Glycerin has been advocated as theoretically indicated in diaceturia, but has not established its claims in practice. Schwarz states that gluconic acid, that is, partially oxidized glucose, has a marked effect in diminishing diaceturia. He has recently published in the *Prag. Med. Wochenschrift*, July 25 and August 1, the account of a young man affected with severe diabetes and pulmonary tuberculosis. He fell into a comatose condition three times in the course of six weeks, with increased acetonuria and dyspnea. The first time, about 70 gm. gluconic acid were administered in a pint of water, neutralized by sodium bicarbonate, after he had lost consciousness. As much as 140 gm. of the latter were also given by the mouth or rectum. He revived at once and his condition remained satisfactory for three weeks, when another attack supervened, arrested in the same way by gluconic acid. Three weeks later a third attack occurred, and as there was no gluconic acid on hand, it was impossible to control it and the patient died. In this case the gluconic acid had evidently saved the patient twice. It seems to serve not only as a food to replace the sugar, but also as a direct curative agent. The case indicates that gluconic acid should be given a trial not merely in coma but also as a preventive measure beforehand. Until gluconic acid has been fully tested, large doses of sodium bicarbonate are the chief resort. It has saved a number of lives in Lepine's experience. One case required intravenous injection of two liters of a solution of sodium bicarbonate.

Bilateral Simultaneous Auscultation of the Lungs. BOURGET.—It is remarkable what delicate differences can be discovered between the two lungs when each ear is provided with a separate tube and funnel for auscultation. The funnels should be placed on symmetrical parts of the lungs. In healthy lungs the sounds blend into one uniform tone, but in case of a lesion in one lung, the difference between the sounds is striking and is most readily perceived by this comparative, simultaneous auscultation.

Centralblatt f. Chirurgie (Leipsic), November 9.

Silver Netting to Close Defect in Trachea. GROSSE.—A girl of 12 suffered from recurring inspiratory dyspnea from a tracheotomy performed nine years before. The walls of the trachea were drawn in during inspiration and the child could get only five to ten minutes' sleep at a time. A piece of silver wire netting, 2 cm. wide and 3 long, was bent to fit the throat and sutured with albumin bronze wire over the defect, outside of the mucosa. The trachea was stretched by this means and held in its normal position. The netting healed into the tissues without reaction and respiration became normal at once and has remained so for the fifteen months since the intervention.

November 16.

Present Status of the Glove Question in Surgery. HEILE.—A single anthrax bacillus may cause the death of a mouse, but in man a certain quantity is required before infection can be induced. This quantity varies with the resistance of the organism and Heile calls it the "infection coefficient," as it varies with every individual. He reports tests with thread gloves which showed that when the hands were much contaminated, the animals all died after protracted operating on them, whether gloves were used or not. But when the hands were scraped and considerable numbers of the germs removed, wearing gloves made a great difference in respect to the survival. Over 45 per cent. of the 34 rabbits in the tests remained alive. Other tests showed that changing the gloves four times during the course of an operation also aided in reducing the number of bacteria in the wound. The more closely woven gloves allowed only 5 per cent. of the germs to pass into the fluid while the old style of loosely woven gloves allowed the passage of 30 per cent. Tricot gloves absorb fluids and bacteria and retain them. They do not allow the passage of any more bacteria than normally alight on the hands or gloves from the air in operating. A number of further tests are reported which show that the entrance of spectators into an operating room immeasurably increases the number of germs. Other tests proved that in changing dressings which have dried on or become adherent from the secretions of the wound or the pus, particles of the dried secretions are flung around and alight on the instruments, and on the blouse aprons of the operator and assistants. The bacteria continue their development on these aprons undisturbed for hours, and thus the wearer of the apron is carrying a dangerous focus of infection around with him. Even fifteen vigorous and separate disinfections of the hands in the course of three days, failed to destroy all the prodigiosus bacteria in the tests described. The best plan therefore is to refrain from contact with septic matters by wearing rubber gloves during septic operations on infected tissues. When this is not possible, thread gloves should be worn during aseptic operations. Rubber gloves are not only unsuitable in aseptic operations, but absolutely dangerous, as there is danger of some slight rip or tear and the hand perspires so freely in them that thousands of bacteria are poured out on the surface of the skin.

Deutsche Med. Wochenschrift, November 14.

Improved Technique for Stethoscopy to Determine the Outlines of Internal Organs. E. REICHMANN.—Supplementing the ordinary methods of percussion and auscultation Reichmann uses a round stick about 7 cm. long by 1 cm. in diameter. The top is flat, the lower end rounded. The space between is cut out like a screw thread; only the grooves are circular, horizontal and parallel instead of spiral. The rounded end is placed on the skin and the forefinger applied to the top, holds it upright firmly pressed against the skin. The fingers of the other hand—not the nails—are rubbed up and down over the grooves while listening through the stethoscope. The sound of the rubbing is very distinct, even when the stick is held a little from the skin, but the moment it is applied over the edge of some internal organ the sound becomes muffled. It is possible by this abrupt change in the sound to locate the outlines of the internal organs with remarkable precision.

Muenchener Med. Wochenschrift, November 12.

New Points of View in the Treatment of Albuminuria. P. EDEL.—The decrease in the albumin during the afternoon in cases of cyclic albuminuria is due to the midday meal. If the hour of the meal is changed, the hours of diminished albuminuria vary with it. When the kidneys show marked albuminuria, and under the most favorable conditions for its production, the administration of potassium acetate will completely arrest it while the organism is under the influence of the drug. This effect on the albuminuria parallels the diuretic action of the acetate. Hot baths have the same influence as diuretics; the urine becomes clearer and more abundant, while the proportion of albumin diminishes. The same

effect is produced by assuming the horizontal position, probably owing to the more favorable conditions for the circulation. Dietetic treatment of albuminuria, alkaline waters, vegetables, etc., probably owes its success to the increased diuresis which it induces. These assertions are the conclusions of much research, the particulars of which are given in tabulated form.

Laryngeal Tuberculosis and Pregnancy. A. KUETTNER.—Seven cases have been published of pregnancy occurring with laryngeal tuberculosis, and Kuettner has collected 15 more. His conclusions from these and 10 or 12 other cases less carefully observed, are that tracheotomy should be postponed until required to prevent suffocation. It should be done as a preliminary to delivery in advanced cases, or at least, should be done during delivery at the first symptoms of suffocation. The earlier the pregnancy is interrupted, the better the chances for the mother. None of the children were born at term, but all were alive and 3 are still living. The mothers all died within two months after delivery, in the cases followed. In 12 of his cases there were no, or minimal, signs of tuberculosis on the part of the lungs; in 3, pulmonary tuberculosis was evident before the pregnancy. In 2 cases the laryngeal tuberculosis appeared in the sixth month, and in 12 in the first half of pregnancy.

Serum Treatment of Basedow's Disease. MOEBIUS.—Serum from animals deprived of their thyroid glands was applied in the treatment of three cases of Basedow's disease, with marked improvement as the result. No albuminuria was observed. Meat from such animals might prove as effective as the serum, Moebius suggests.

Wiener Klin. Wochenschrift, November 14.

Influence of Diet on Course of Epilepsy. H. SCHLOESS.—A medical writer in the time of Trajan called attention to the unfavorable influence of a meat diet on the course of epilepsy. Schloess, after considerable study of the subject, found that an exclusive milk and vegetable diet had as little influence in diminishing the number of the attacks as a meat diet in increasing them. Depriving epileptics of salt in their food during the administration of the bromids, always reduced the number of the seizures. The psyche is not affected by this measure, but the patients lose in weight and become weak. Fats and acids and the moderate use of alcohol, as much as a liter of light beer during the day, had no influence in increasing the number of the seizures.

Juvenile Tabes. H. V. HALBAN.—Tabes can not develop without preceding lues; this statement of Halban's is based partially on the development of tabes in three cases of juvenile syphilis, inherited or acquired in infancy. The symptoms were about the same in all three and the cases were distinguished by the remarkable absence of subjective disturbances. The patients applied to the physician for some other reason than the incipient tabes, which he at once recognized. The youthful nervous system probably reacts differently to syphilitic intoxication than the adult.

Revista Med. del Uruguay (Montevideo), September.

Surgery of the Lung. J. H. OLIVER.—Only seven cases of tubercular cavities in the lungs communicating with an abscess in the costal wall, have been reported in the literature according to Oliver. In three the cavity was an operative surprise, as the intervention had been undertaken merely for the relief of the external abscess. In these cases there was no communication between the abscess, the cavity and the air passages. Tuffier has stated that only 13 survived out of 26 cases of tubercular cavities he has operated on and only one for more than five years; two died the second or third year; the others were followed for only two or three months. Only one of Hahn's four or five patients has survived ten years. The mortality was 20 per cent. in the cases of cavities communicating with an external abscess, and the ultimate results are no more favorable than in the other categories. Oliver reports a case diagnosed and operated on as a "shirt-stud" tubercular abscess. The tubercular cavity below was not found until at a second operation. The symptoms of the disease vanished after the intervention, and complete clinical recovery has persisted to date, more than eight and one-half years after the intervention. The patient has been a carpenter and is now working in the dust of a tobacco factory, with no recurrence of the old symptoms, not even after a severe intercurrent attack of la grippe.

Books Received.

BERICHT Ueber die in der Züricher Chirurgischen Klinik in den Jahren 1881-1900 Behandelten Fälle von Offenden Wunden des Abdomens. Inaugural-Dissertation zur Erlangung der Doktorwürde der Hohen Medicinischen Fakultät der Universität Zurich, vorgelegt von George Howard Hoxie, aus Cambridge, New York, U. S. A., Genehmigt auf Antrag der Herrn Prof. Dr. Krönlein. Paper. Pp. 54. Tübingen: Druck von H. Laupp, Jr. 1901.

ANATOMY IN ITS RELATION TO ART. An Exposition of the Bones and Muscles of the Human Body with Especial Reference to Their Influence Upon Its Actions and External Form. By George McClellan, M.D., Professor of Anatomy of the Pennsylvania Academy of Fine Arts. Illustrated by 338 Original Drawings and Photographs Made by the Author and Expressly Prepared for This Work. Cloth. Pp. 133. Price, $10.00. Philadelphia and London: W. B. Saunders & Co. 1901.

AN INTRODUCTION TO THE CHEMICAL ANALYSIS FOR STUDENTS OF MEDICINE, PHARMACY AND DENTISTRY. By Elbert W. Rockwood, M.A., M.D., Professor of Chemistry and Toxicology in the College of Medicine. Illustrated. Cloth. Pp. 255. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1901.

Queries and Minor Notes.

DENTAL CARIES IN PREGNANCY.

PHILADELPHIA, Nov. 14, 1901.

To the Editor:—Kindly give me information in regard to the literature, essays, etc., pertaining to the subject of the preventative treatment of caries of the teeth occurring in pregnancy and lactation. S. L. F.

ANS.—The principal literature on the subject is to be found in the files of dental journals. There is little to be found in textbooks.

NOTICE OF CHANGE OF RESIDENCE.

CHARLOTTE, W. VA., Nov. 23, 1901.

To the Editor:—Recently, I changed my residence from Point Creek to this city to practice my profession. Will you please advise me if I would be doing anything ethically wrong to insert a card in the daily papers notifying my friends and patients of the change? H. G. N.

ANS.—It is always a good plan when one is in doubt to err on the right side. The fact of making the inquiry shows that our correspondent's conscience is pricking him a little. It would be much better to send a card announcing his removal to his patients rather than to insert a card in the newspapers.

ENGLISH DISTINCTION OF DR. AND MR.

ELK RIVER, MINN., Nov. 30, 1901.

To the Editor:—Will you kindly explain why some English physicians bear the title of "Mr." and others that of "Dr."? Conan Doyle, the novelist, is Dr. Conan Doyle; Sir Joseph Lister, the eminent surgeon, is Mr. Lister. Why is the distinction?

C. Q. S.

ANS.—Generally speaking, those who are designated "Mr." are supposed to be surgeons, and "Dr.," physicians. No one has a right to the title "Dr." unless he holds a Doctor's degree. The M.D. degree is conferred in Great Britain and Ireland only by Universities, and is preceded by the bachelor's degree. The right to practice is conferred by various bodies, among these being the Royal College of Surgeons, the Royal College of Physicians of London, and the Royal College of Physicians of Edinburgh. These grant L.R.C.P. or S., M.R.C.P. or S., F.R.C.P. or S. degrees, which do not carry with them the title of "Doctor." Arthur Conan Doyle, the author, received the M.B., C.M., in 1881, and the M.D. from the University of Edinburgh, in 1885. Joseph (now Lord) Lister received the B.A. degree in 1847, the F.R.C.S. and M.B., in 1852, and various other degrees since then, but not the M.D. until it was conferred (honoris causa) by Trinity College, Dublin, in 1879. After this Lister was entitled to the title "Doctor."

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Nov. 21-27, 1901, inclusive:

Roger P. Ames, captain and asst.-surgeon, Vols., leave of absence for two months granted.

Bailey K. Ashford, lieutenant and asst.-surgeon, U. S. A., former orders, relieving him from duty at Fort Slocum, N. Y., and assigning him to duty in the Department of Cuba, revoked.

Alexander F. Bacon, contract dental surgeon, now in Washington, D. C., to proceed via Tampa, Fla., to Havana, Cuba, for duty in the Department of Cuba.

David Baker, lieutenant and asst.-surgeon, U. S. A., former orders so amended as to relieve him from duty on the transport *Meade*, and from further duty in the Division of the Philippines, to assign him to duty in the Department of California.

James L. Bevans, contract surgeon, from duty at the General Hospital, San Francisco, Cal., to Decatur, Ill., for annulment of contract.

Marshall M. Cloud, lieutenant and asst.-surgeon, U. S. A., from Fort Sill, Okla., to post duty at Fort Leavenworth, Kan.

Peter C. Field, lieutenant and asst.-surgeon, U. S. A., from Fort Slocum, N. Y., to duty at Fort Robinson, Neb.

Arthur C. Heffenger, contract surgeon, now at Portsmouth, N. H., is assigned to duty at Fort Constitution, N. H.

Edward F. Horr, captain and asst.-surgeon, Vols., leave of absence for two months granted.

Thomas A. Marshall, captain and asst.-surgeon, Vols., recently appointed and now at Bedford City, Va., to proceed via San Francisco, Cal., to Manila, P. I., for duty in the Division of the Philippines.

John A. Murtagh, lieutenant and asst.-surgeon, U. S. A., from the general Hospital, Presidio of San Francisco, Cal., to report to the commanding officer at Fort Columbus, N. Y., for temporary duty with troops sailing for Manila, P. I., on the transport *Buford*, about Jan. 15, 1902. On arrival at Manila, he will report for assignment in the Division of the Philippines.

Henry Page, lieutenant and asst.-surgeon, U. S. A., member of an examining board at Fort Monroe, Va., vice Lieut.-Col. Robert M. O'Reilly, deputy surgeon-general, U. S. A., relieved.

David M. Roberts, contract surgeon, from temporary duty at Fort Bliss, Tex., to duty at Fort Sam Houston, Tex.

Erle H. Sargent, contract surgeon, from Vancouver Barracks, Wash., to San Francisco, Cal., en route to Manila, P. I., for assignment in the Division of the Philippines.

Albert H. Simonton, contract surgeon, from Fort Robinson, Neb., to Birmingham, Ala., for annulment of contract.

Charles F. Williams, contract surgeon, relieved from duty at Fort McPherson, Ga., to accompany the First Battalion of the 27th Infantry en route to the Philippine Islands, and to report at Manila, P. I., for assignment to duty in the Division of the Philippines.

APPOINTMENTS, PROMOTIONS, RETIREMENTS, ETC.

Regular Army Appointments.—To be assistant-surgeons, with the rank of first lieutenant, dating from Oct. 12, 1901: Wilfrid Turnbull, of Pennsylvania. Dating from Oct. 30, 1901: Walter C. Chidester, of Ohio; Reuben B. Miller, of Illinois; Charles A. Ragan, of Tennessee; William R. Eastman, of Virginia; George W. Jean, of Kentucky; James F. Hall, of Massachusetts; Raymond F. Metcalfe, of New York; Edwin W. Rich, of Massachusetts; Perry L. Boyer, of Virginia, and James L. Palmer, of Illinois.

Promotions.—Major Valery Havard, surgeon, to be deputy surgeon-general, with the rank of lieutenant-colonel, Oct. 24, 1901; Captain Ogden Rafferty, asst.-surgeon, to be surgeon, with the rank of major, Oct. 24, 1901. The following-named assistant-surgeons were advanced to the grade of captain, Oct. 26, 1901, by reason of having served five years: Basil H. Dutcher, Leigh A. Fuller, Franklin M. Kemp, George A. Skinner, and Carl R. Darnall.

Retirements.—Lieutenant-Colonel Ezra Woodruff, deputy surgeon general, Oct. 24, 1901.

Wholly retired, for disability not incident to the service: First Lieutenant Henry E. Wetherill, asst.-surgeon, Oct. 16, 1901.

Resignations.—First Lieutenant Clarence B. Millhoff, asst.-surgeon, Nov. 5, 1901.

Volunteers, Appointments.—To be surgeons, with the rank of major: John C. Greenewalt, of Pennsylvania, Sept. 20, 1901; Captain George B. Lawrason, asst.-surgeon, Oct. 10, 1901; Captain Charles B. Nichols, asst.-surgeon, Oct. 31, 1901; Captain Charles H. Andrews, asst.-surgeon, Oct. 31, 1901; Captain Matthew Leepere, asst.-surgeon, Nov. 5, 1901, and Frank H. Titus, of California, Nov. 5, 1901. To be assistant-surgeons, with the rank of captain: Luther S. Harvey, of Florida, Aug. 12, 1901; Edwin M. Trook, of Indiana, Sept. 21, 1901; William P. Baker, of Oklahoma, Oct. 2, 1901; Josiah M. Ward, of North Carolina, Oct. 10, 1901; Frank L. R. Tetamore, of New York, Oct. 10, 1901; Edward N. Bowen, of Massachusetts, Oct. 23, 1901; Luke B. Peck, of Massachusetts, Nov. 5, 1901, and Harry A. Eberle, of Ohio, Nov. 8, 1901.

Honorably Discharged.—Captain Frank P. Kenyon, asst.-surgeon, Oct. 23, 1901, and Major Ernest K. Johnstone, surgeon, Nov. 2, 1901.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Nov. 30, 1901:

Asst.-Surgeon J. J. Snyder, ordered home and granted three months' sick leave.

Asst.-Surgeon Edgar Thompson, detached from the Naval Hospital, Chelsea, Mass., and to duty at the Charleston Exposition in charge of the exhibit of the Medical Department of the Navy, and in attendance on the Marine Guard and the Marine Recruiting Rendezvous.

Medical Director R. C. Persons, commissioned medical director from Nov. 3, 1901.

Medical Inspector E. H. Green, commissioned medical inspector from Nov. 3, 1901.

Surgeon N. H. Drake, detached from duty as member of the Medical Examining Board, Naval Laboratory, New York, and ordered home to wait orders.

Surgeon A. C. H. Russell, ordered to duty as member of the Medical Examining Board, Naval Laboratory, New York, December 4.

Asst.-Surgeon D. G. Beebe, resignation accepted, to take effect Nov. 30, 1901.

Asst.-Surgeon Edgar Thompson, commissioned a P. A. surgeon from April 19, 1901.

Dr. J. B. Buchanan, appointed an asst.-surgeon in the Navy from Nov. 23, 1901.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Nov. 30, 1901:

SMALLPOX—UNITED STATES.

California: San Francisco, Nov. 10-17, 1 case.
Illinois: Chicago, Nov. 16-23, 4 cases.
Indiana: Evansville, Nov. 16-23, 2 cases.
Louisiana: Nov. 16-23, New Orleans, 10 cases, 1 death; Shreveport, 3 cases.
Massachusetts: Nov. 16-23, Boston, 37 cases, 4 deaths; Cambridge, 3 cases; Chelsea, 1 case; Everett, 1 case; Newton, 1 case; Somerville, 1 case.
Minnesota: Minneapolis, Nov. 9-23, 5 cases.
Missouri: St. Joseph, Sept. 1-Oct. 31, 80 cases.
Nebraska: Omaha, Nov. 16-23, 4 cases.
New Jersey: Camden, Nov. 16-23, 1 case; Jersey City, Nov. 19-26, 9 cases; Newark, Nov. 18-25, 25 cases, 2 deaths.
New York: New York, Nov. 16-23, 6 cases, 1 death.
Ohio: Nov. 16-23, Ashtabula, 1 case; Cincinnati, 3 cases.
Pennsylvania: Allegheny City, Nov. 16-23, 2 cases; Lebanon, Nov. 16-23, 2 cases; Norristown, Oct. 12-Nov. 23, 39 cases, 5 deaths; Philadelphia, Nov. 16-23, 46 cases, 7 deaths.
Tennessee: Nashville, Nov. 16-23, 1 case.
Utah: Salt Lake City, Nov. 9-23, 4 cases.
Vermont: Burlington, Nov. 16-23, 1 case.
Washington: Tacoma, Nov. 9-16, 1 case.
Wisconsin: Green Bay, Nov. 17-24, 6 cases.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, Sept. 1-30, 93 deaths.
Brazil: Pernambuco, Oct. 1-15, 74 deaths.
Canada: Nova Scotia, Halifax, Nov. 16-23, 10 cases.
Colombia: Cartagena, Nov. 4-11, 3 deaths; Panama, Nov. 11-18, 125 cases.
France: Nice, Oct. 24-31, 2 deaths; Paris, Nov. 2-9, 4 deaths: St. Etienne, Oct. 18-31, 1 case.
Great Britain: Glasgow, Nov. 9-16, 1 case; London, Nov. 2-9, 297 cases, 19 deaths.
Russia: Moscow, Oct. 26-Nov. 2, 16 cases, 2 deaths; Odessa, Nov. 2-9, 5 cases, 2 deaths; St. Petersburg, Oct. 26-Nov. 9, 4 cases, 1 death; Warsaw, Oct. 26-Nov. 2, 1 case.
Spain: Malaga, Oct. 26-Nov. 2, 4 deaths.
Uruguay: Montevideo, Sept. 21-Oct. 12, 161 cases, 15 deaths.

YELLOW FEVER.

Brazil: Pernambuco, Oct. 1-15, 1 death.
Mexico: Merida, Oct. 26-Nov. 2, several cases; Valladolid, Oct. 26-Nov. 2, several cases; Vera Cruz, Nov. 9-23, 41 cases, 12 deaths.

CHOLERA.

India: Bombay, Oct. 22-29, 1 death; Calcutta, Oct. 12-26, 55 deaths; Madras, Oct. 19-25, 40 deaths.
Java: Batavia, Oct. 12-19, 25 cases, 20 deaths.

PLAGUE—FOREIGN AND INSULAR.

Great Britain: Liverpool, Nov. 7, 1 death.
India: Bombay, Oct. 22-29, 191 deaths; Calcutta, Oct. 12-26, 36 deaths; Karachi, Nov. 13-20, 20 cases, 9 deaths.
Russia: Odessa, Oct. 31-Nov. 9, 1 death.
Hawaiian Islands: Honolulu, Nov. 8-10, 1 death.

THE EVALUATION OF ANTHROPOMETRIC DATA.*

WINFIELD S. HALL, PH.D. M.D.

Professor of Physiology, Northwestern University Medical School. CHICAGO.

The term anthropometric data may be applied to the numerical results of all observations on the structure or functions of man, i. e., such observations as: weight, height, and bone lengths in general; girth of head, body or limbs at the different levels; lateral or dorso-ventral diameters of trunk at different levels; facial measurements, including facial angles; cranial measurements: pelvic measurements; strength tests; acuteness of vision, of hearing, of feeling, and of taste; time of sense-reaction; pulse rate; blood pressure; respiratory rate; expansion of chest; lung capacity, and amount of tidal air; number of corpuscles per unit volume of blood: percentage of hemoglobin of blood, etc. These are the more important groups of anthropometric data.

A glance at the wide field covered by such data makes it evident that a very large proportion of the research work done by medical men involves the recording of numerical data. There may be cited, for example, the following lines in which such data are recorded: the medical examination of school children; medical examination of army and navy recruits; insurance examinations; medical examination for certain positions in the civil service; medical examinations in college, Y. M. C. A. and private gymnasia; bone measurements in surgical practice; certain facial measurements, in ophthalmology; pelvic measurements, in obstetric practice · cranial measurements, in criminology and in hospital practice in mental diseases; many of the problems of pedology, pediatrics and orthopedics; and finally, clinical diagnosis and pharmacology; in short, almost every department of medical practice requires, at least, the occasional use of anthropometric data.

In these various fields of work great quantities of data have been collected and are being collected without being put to any use. The collection of such data is likely to be looked upon as a part of the routine in taking a case history; and, though in some instances valuable for subsequent reference, such instances are rare and the enthusiasm of the physician gradually abates as he finds that the accumulating statistics are never used. The result is that the statistical work is wholly dropped or reduced to the minimum in the case of the private physician or the specialist; while it is continued in a most mechanical and perfunctory manner by those conducting medical examinations in public institutions.

In those fields, e. g., criminology and pedology, where the anthropometric data have been carefully collected and properly utilized, general truths of very great value have been discovered. There is no reason to doubt tha if the other fields were properly worked, they would prove equally fruitful. The whole difficulty rests with the methods which are in vogue for handling the accumulated data. The recorded data have only a potential value. One may make thousands of observations, but he can draw no conclusions from them until he groups and summarizes them.

This last-mentioned process is an essential one and may be called the evaluation of anthropometric data.

OLD METHODS.

In evaluating anthropometric data, it has been generally customary to group the individuals into classes and to find the arithmetrical mean or the average of the measurements or other data for each class. This involves the tabulation of the observations on the individuals of each class so that similar observations stand in vertical columns. The tabulation of the statistics is a long and wearisome task, but when one remembers that when the tabulation is complete, the work is only just begun and that every spare hour for weeks and months must be devoted to the exhausting work of adding columns of figures, he does not wonder that busy clinicians and medical examiners in the various institutions become discouraged in their attempts to get anything of value out of the statistics which they have so carefully collected.

The object of this paper is to outline a short and yet mathematically accurate method of evaluating the data —a method so simple that any school boy can apply it with small chance of error, and so easy that the oft-interrupted and preoccupied practitioner can use it at odd moments and while he is resting.

THE NEW METHOD.

The Belgian astronomer and anthropologist, Quételet,[1] was first to call attention to the fact that the arithmetical mean or average is of less value than the median value. The *median value* is that value which is so located in the whole series of observations of a single measurement of any group that there are as many below it as above it; i. e., that the number of values which it exceeds is equal to the number of values which exceed it. For a concrete case, suppose we wish to find the height of nine men taken at random from any audience.

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Physiology and Dietetics, and approved for publication by the Executive Committee.

1. Anthropometrie, ou mésure des diff. facultés de l'homme, Bruxelles, 1870.

Let their heights be 162, 164, 166, 168, 170, 172, 174, 176, 187 cm. The average is 171 cm., but the median or middle value is 170 cm. Which of these results is the more valuable? It so happened that there was a very tall man among those chosen and his height raised the average 1 cm. above the median value. Had there been a very short man instead, the average would have fallen below the median value. If a large number of individuals are observed, the chances are that there will be as many very short men as very tall ones so that the average will approach the median as the number of observations increase. For a small number of observations, then the median must be conceded to have more value than the average. But how shall we determine this median value?

In the first place the data must be recorded upon cards. Case data which are largely anthropometric, as in physical examinations in the army, navy or the gymnasium, may be recorded at once upon cards. Most clinicians record data upon clinical history sheets and file them alphabetically or otherwise. Any numerical data, first recorded upon clinical history sheets and which it may be desired to use, may be copied upon cards in order that the files shall not be disarranged.

The cards containing the data may be grouped as desired. Let us suppose that a school medical examiner has recorded upon cards the height, weight, head girth, chest girth, lung capacity, acuteness of vision and of hearing, for 10,000 school children. Each individual is represented by a card. The individuals may be grouped first as to sex. Let each sex be grouped as to age, and each age as to nationality, or social position of parents. Suppose there are 314 boys of 16 years representing families which had been for several generations in America. Such a group of individuals could be looked upon as a homogeneous group. How shall we determine their median girth of head? Let us arrange the cards in groups, putting in one pile all whose head girth is 50 cm. or fraction of a centimeter; in the next group, cards which bear a record of 51+cm. and so on, the result being as shown in the following table:

Girth of Head of 16-year-old American Boys.

Measurement.	50+	51+	52+	53+	54+	55+	56+	57+	58+	59+	60+	61+
No. of observations .	1	3	13	28	34	73	69	52	26	11	3	1

The total number of observations being 314, we have only to locate and determine the value of the 157th measurement from either end. Adding the observations from left to right (1+3+13+28+34+73=152) we find that the middle individual must be in the group whose head girth is 56+cm. This may be called the Median Group. Moreover, the middle individual is the 5th one in this group from the left or the 64th from the right. Now the 69 individuals of this median group have head girths ranging from 56 cm. to 57 cm. and according to fundamental biologic laws, they will be practically evenly distributed through this 1 centimeter. The 5th individual from the left must then have a head girth of 56 5/69 cm. or 56.072. This is the solution complete, and it could be easily obtained in twenty minutes, whereas to copy the numbers in columns and add them would require hours of the most fatiguing toil.

If it is desired to reduce this simple process to a mathematical formula, that can be readily done:

Let n = the total number of observations (314); m = the number of observations in the median group (69); l = the sum of the observations at the left of the median group r = the sum at the right; a = minimum value of the median group (56 cm); d = arithmetric difference in the minimum values of the groups d = 1 cm. in above, and m = median value to be determined.

Then:

$M = a + [d\ (n \div 2 - l) \div m]$.

$M = 56 + [1\ (314 \div 2 - 152) \div 69] = 56\ 5\text{-}69 = 56.072$ cm.[2]

THE SIGNIFICANCE OF THE RESULTS.

But this question of the median value is broader than a simple statistical problem—it is based upon fundamental, biologic and mathematical laws. One could hardly follow the steps in the above presentation without noting that the number of observations for each separate value increases progressively from the two extremities toward the middle of the series where the maximum is represented by one large value or by two large and nearly equal values. Francis Galton[3] called especial attention to this and published figures to illustrate this law of distribution of values. The law may be formulated thus: Any structural dimension or functional property of any species of living thing tends to approximate a fixed standard or middle value, while the others will progressively shade down to a maximum in one direction and to a minimum in the other. This may be called the *law of distribution of biologic data*, understanding, of course, that it is the distribution of data concerning any one structural feature or functional property within any one species of plants or animals.

Table 2 shows the distribution of head girths of 1071 youths from 16 to 19 years old.

Table 2.—Head-girth, Boys 16-19.

Measurement. . . .	51	52	53	54	55	56 56.46	57	58	59	60	61	
No. of observations.	4	23	59	108	224	257	230	110	38	16	2	1071
Coeff. $(a+b)^{10}$. . . .	1	10	45	120	210	252	210	120	45	10	1	1024

The distribution of these measurements illustrates the above formulated law. The computed median value is 56.46 cm. Note that of the 1071 observations, 711 of them fall within 1.46 cm. below and 1.54 cm. above the median value, while the 360 remaining observations "progressively shade down to a maximum (61 cm.) in one direction (110—38—16—2) and to a minimum (51 cm.) in the other." Figure 1 shows the 1071 cards distributed in the different groups as indicated in Table 2.

Table 2 shows a third series of values, viz., the coefficients of a binomial raised to the tenth power. If the expression a+b were squared—$a^2+2ab+b^2$—and this multiplied by a+b and so on to the tenth time, an expression of eleven terms would result and the coefficients would be 1—10—45—120, etc., as shown in the table. The sum of these coefficients equals 1024. If one compares this series of coefficients with the series of observations in the line above them he notes a remarkable parallelism. Now this is not the result of a rare chance: it is in conformity to a natural law. It transpires then that the law of the distribution of biologic data is the law of the series of binomial coefficients. The corres-

2. E. W. Scripture, Psychological Review, vol. ii, p. 376, under title, "Practical Computation of the Median," gives the formula: M=a+[l—r÷2 m.]. Subjecting Scripture's formula and my own to repeated tests, I find that the former is less accurate; i. e., both formulæ are approximations, but the one given above is the closer approximation and gives results within .2 of 1 per cent. of the real median while Scripture's formula often varies as far as 1 per cent. from the real median.

3. Natural Inheritance, London, 1889.

pondence of these series is made graphic in Figure 2 where the values are plotted in the form of a curve. Even with a thousand observations, the curve of distribution corresponds very nearly to the binomial curve: if there were ten thousand measurements it is certain that the two curves would be perfectly coincident.

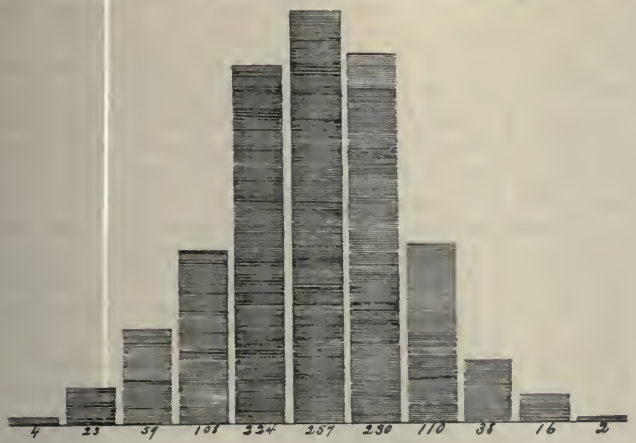

Fig. 1.—Showing the 1071 cards grouped as to the size of head-girth; the middle stack shows that 257 boys had a head-girth equal to 56 cm., but less than 57 cm. See Table 2 for other facts regarding figure.

The odd powers of a binomial 1st, 3d, 5th, 7th, etc., have an even number of terms and two equal maximum coefficients instead of one maximum coefficient. This feature of the binomial series also corresponds to something very frequently found, namely, that there is no one pile that is clearly the maximum pile, but that there are in the middle of the series, two maximum piles of fairly equal size.

What is the significance of this remarkable coincidence between the curve of binomial coefficients and that of the distribution of biologic data? This is a problem the solution of which belongs to the biologist rather than to

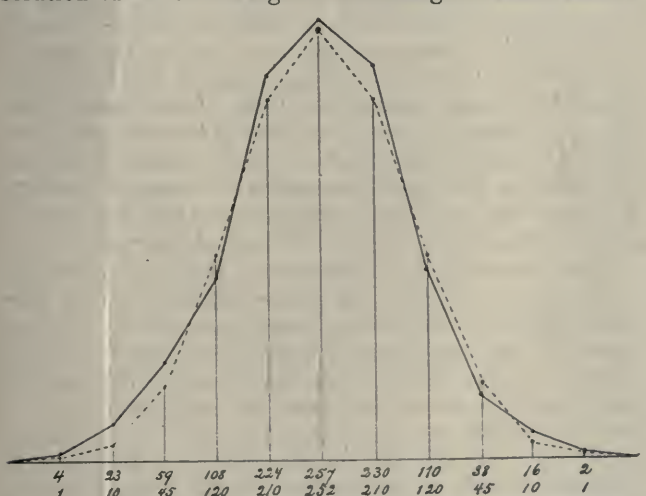

Fig. 2.—Showing the relation between the curve of biologic distribution and that of the binomial coefficients. The former is represented by the continuous line plotted from the upper line of figures and represents the distribution of 1071 boys with reference to girth of head; the median girth being 56.46 cm. The curve of binomial coefficients is represented by the dotted line and is plotted from the coefficients of $(a+b)^{10}$. This set of coefficients being chosen because their sum (1024) most closely approximated the number of individuals represented in the biologic distribution curve.

the mathematician. By way of suggestion, simply, the reader may be reminded: 1, that the principal biologic factor in determining specific characters is heredity; 2, that heredity involves a double influence—the father plus the mother—which may be represented mathematically as a+b; 3, that when a value is influenced by a series of variable factors it is found in mathematics that it would vary as the product of these factors. The only way heredity can act in a series of influences is in the series of succeeding generations which may be represented as a+b, a+b, viz., the paternal, (a), and maternal, (b), influences of the successive generations. The total influence of heredity could then be represented by $(a+b)\times(a+b)\times(a+b)$ to the nth power. If the coefficients of this product be plotted they will describe the curve shown in Figure 2. If the numerical data arising from the measurement of any one feature of the lineal descendants of the nth generation of an original father and mother (a+b) be grouped as in Table 2 and the numbers plotted, the curve will closely approximate or actually coincide with the binomial.

SUMMARY.

1. The collection of anthropometric data is almost universal in the practice of medicine. In the case of certain special lines of work these data are of fundamental importance.

2. Anthropometric data have a potential value, but no practical value as such. Only through some process of evaluation can the potential value be made practical and form the basis of general conclusions.

3. That method of evaluation which involves the use of arithmetical average is both time wasting and inaccurate, while the method based on Quételet's Median value is accurate, and is quickly and easily applied.

4. The median value is the value represented by the median measurement of a series of measurements; that is, that measurement which has as many values above it as below it.

5. The above described method of evaluating anthropometric data should be of value to all surgeons, pathologists, physiologists, and psychologists: to medical examiners in schools, gymnasia, insurance companies, the army and the navy; and to criminologists, neurologists, and anthropologists.

DISCUSSION.

DR. JOHN MADDEN, Milwaukee—Some one has said there is a divinity in the mathematical equation. Surely there is a divinity in mathematical precision as applied to anthropology as everywhere else. While Professor Hall was reading his paper it occurred to me that the mean measurement that is obtained after examining many hundreds of thousands of children should be kept in mind. That I suppose is the purpose of the measurement, to ascertain what a healthy, normal child of a definite age should measure and weigh and what he should be like. I presume that if we measured a great many million children we would get a definite mean. I do not know whether the mean measurement obtained west of the Rocky Mountains would hold good for the whole country, but the practical application is that if a child is brought to you and he has the marks of being abnormal you have at once at your fingers' ends the mean measurement of a normal boy at his age, and you measure him just as you would measure with a rule and square. If he does not vary from the established mean he is considered a good specimen. If, on the other hand, he does vary; if there is a certain group of measurements in which he does not correspond to the mean measurement, you have the full line of ancestry, environment and other considerations to investigate and put yourself in possession of accurate knowledge to enable you to do what is possible for the child. In a paper which I have just written I have touched upon this subject, and it seems to me that something of what the Doctor has shown this afternoon should be in the books of the schools so that from the time the child enters school until the time that he goes out into the world it should be know what he has been. Then when we come to do anything for him, should he be a degenerate, we can put our finger upon the cause. We can

tell whether the trouble is in his environment, heredity or disease. While the beauty and the interest of the mathematical demonstration appeal to me, nothing appeals more forcibly than the importance of the measurement itself from a practical standpoint to be used every day by the physician.

DR. H. S. DRAYTON, New York City—I consider the work of the anthropologists and ethnologists, especially their custom of measuring brains and skulls, as vastly inferior to the method illustrated by Dr. Hall. Taking 150 or more crania of different races, measuring them by tape line and calipers in certain regions, and then striking a general average by dividing the aggregate measurements by the number of specimens, has been a procedure that scientific men appeared to be well satisfied with. This modern method, however, with its mathematical accuracy and differential applications, as shown us by Dr. Hall, demonstrates very definitely the crudity of old procedures, and discounts their statistical value.

DR. HALL, in reply—I think possibly I did not emphasize sufficiently that the whole object of this method is to accomplish what Professor Madden had in mind—the application of it by the men who are in position to collect large masses of data for statistical tables—showing in tabular form the evaluations for various groups of individuals, these to be published for the use of medical school examiners over the country. We are now in possession of considerable data, but we are only in the beginning because there has not been enough accurate and scientific grouping done. The average of 20,000 St. Louis children does not signify very much. The children should have been grouped first in various nationalities, and according to social conditions, besides being grouped according to ages. We want the practical application and not the theoretical.

THE EDUCATION OF THE DEGENERATE.*

JOHN MADDEN, M.D.
MILWAUKEE, WIS.

Those nerve cells which are most active, develop most in increasing length and complexity of their dendritic branches. The development takes place during physical as well as mental activity, and the education of one cell group, directly stimulated, leads to the education of more or less remote cell groups, by reason of dendritis contact. No matter, then, whether we reach the brain through the avenues of mental or physical activity, we shall have made a commencement in the education of the child just as soon as we can make him do something. If he be defective in mental development, in the development of the cells of the higher centers of the brain, and it is found that they can not be directly stimulated, then we must try to reach them indirectly, stimulating those of the motor area by muscular exercise. "If we wish to hasten the maturity of the brain, we must decide whether the formation of the myelin sheath can better be hastened by stimulation of the senses and intellectual work, or better, by muscular exercise. The latter way seems the more natural. We must, therefore, to begin with, consolidate the motor nerve paths which develop first, and after that seek to develop the portion of the brain concerned with intellectual work. Modern views show a tendency to confirm what the great philosophers of Greece already recognized, viz., that children ought to begin to read and write only with the tenth year. The conviction is again slowly maturing that our children begin too early, that it is injurious for the development of the brain to be fettered to the school desk when only 5 or 6 years old. The conviction is slowly making its way that no more time should be devoted to intellectual work than to muscular exercise. The modern education of youth, however, resembles more an artificial hot-house culture than a natural training of the human plant."[1] Muscular activity alone develops intelligence, the more complicated and varied the movements, and the greater the period of time over which they are extended—up to the age when development ceases—the better will the individual be educated on his purely mental side. Everyday observation confirms this view. The skilled mechanic of no book learning is generally a man of superior intelligence, a man of accurate judgment, good reasoning powers, and good morals. Here in America the mechanic, native born, has almost always a good, common-school education and is a diligent reader. In England, however, it is not uncommon to find skilled laborers devoid of book learning, yet men of no little intellectual force. The children, too, of such men often display intelligence of a high order and become brilliant scholars. They are, indeed, sometimes pointed out as exceptions to the rules of heredity, by those who fail to see the unity of physical and mental stimuli in brain development.

Often, indeed, some simple muscular movements are all that the unfortunate defective can be taught to carry out; it is the one breach which can be made in the wall which separates him from the ordinary physical and mental activities of mankind; but through this single avenue some development is generally possible. Said Dr. Martin W. Barr,[2] chief of Pennsylvania Training School for Feeble-Minded Children: "The motto of the schools—'We learn by doing; the working hand makes strong the working brain'—shows manual training to be the basis of the scheme of development, varied for each grade to suit the intelligence."

In the Elmira Reformatory equally good results are obtained in reaching the higher centers from the physical side. The defectives are divided into three classes: 1, those who are intellectually weak, but have powers of self-control; 2, those who are bright, but lacking in self-control, and 3, those who are weak, and also lacking in self-control. Great benefit has resulted to them from physical training, especially to those of the second class. Nearly all graduate with sufficient self-control from the manual trades' department to be put into the trades' school. The history of one particular case, No. 6.361, is given. He was a dangerous criminal who was made a good citizen by this system of manual training.

That "Satan can find something still for idle hands to do" is an old saw with a new interest; for we now understand that it is not so much the fault of the idle hands as the undeveloped brain resulting from that idleness. This, then, is our brief upon which we ask that every district school have the apparatus and instructors to educate the physical as well as the mental side of our children; not only for the reason that normal children need the physical education, but because certain defectives, certain incorrigibles may be educated and made useful through muscular activity when all attempts at education through merely mental processes fail.

But the work of our schools should go further than this. Just as it is the physician's duty not only to cure members of a family already afflicted with disease, but to make the conditions such that no others shall contract it, so the teacher shall do what he may to lessen the number of defective members of society; for, after all, where and during what period of life can matters relating to personal hygiene, which has so much to do with

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Physiology and Dietetics, and approved for publication by the Executive Committee: Drs. James Weir, Jr., Winfield S. Hall and Elmer Lee.

NOTE: This paper is a part of one chapter of a book which will soon be published under the same title.

insuring a sound body and a sound progeny, be better and more thoroughly inculcated than with the impressionable youth of the common schools? And it is encouraging to note that school men are alive to the importance of this question. Two years ago there came from a man who assumed the right to speak authoritatively on the subject, the edict that our youth were not being properly instructed in regard to the effects of alcohol upon the human system, that it is not a poison as is generally taught, but may, indeed, be the only food remedy which, under certain circumstances, will save life. As the alcohol question is by far the most important factor in the teaching of personal hygiene in our schools, this verdict aroused an enormous amount of discussion. This man went before the assembled school superintendents of the country and made an indirect plea for alcohol, teaching that it was a food and not a poison except when taken in excess. This he has reiterated in the columns of the lay press. So great was his influence that the School Superintendents' Association appointed a committee of seven of their members to inquire into his indictment of anti-alcohol teaching in our schools. It is encouraging to know that this committee utterly repudiated the indictment. Not only this, but they recommended, "that the scope of the investigation be so enlarged as to cover not only the topics already suggested, but the whole field of personal hygiene." This they declared after previously extinguishing the special plea for alcohol as follows: "The question of the supposed food value of alcohol is a technical one for medical—not for chemical—experts to determine and not one which needs to concern the man and woman who are engaged in the work of public instruction of children and youth. For them it is enough to know that its use as a beverage is injurious and that all authorities agree in deprecating the formation of the drinking habit, and in commending all practical efforts, through public instruction, to promote the cause of temperance."

Moreover, schools could greatly contribute toward the study of degeneracy by gathering statistics of all children who attend them. For instance, they could have written, with little trouble, in books prepared for the purpose. each child's status when he entered school. Let them cover such questions as physical development and state of health; whether parents are living and their condition of health; whether any brothers or sisters are dead, ill, or in any way mentally or physically incapacitated; whether the race from which he descends is long or short lived; and, if notably short-lived, what has been the chief cause of death; whether any relatives near or remote were insane, imbecile, tuberculous, syphilitic, or alcoholics; what the occupation and habits of the parents; what their social status; and lastly, what is the child's environment? Knowledge of this kind would be of enormous advantage, not only to the teacher, but to society at large, for each individual would then have a tangible record and any shortcomings on his part in more mature years could be traced to their proper causes and adequately treated.

Very valuable statistics of the social and moral status of the parents of industrial and reformatory school inmates are gathered in England and Scotland by those who are officially appointed to collect contributions from the parents for the inmates. These collectors see the parents in their homes at stated intervals, for a period of years, and learn, as far as it is possible for an outsider to learn, the real character and surroundings of the offender's immediate ancestors. "It was stated by Mr. McDonald, one of those agents, in reply to a question of the Royal Commission, that only 6 per cent. of the children in the industrial schools had homes fit to live in. Mr. McDonald's experience related to the parents of Scotch children; in some parts of England the percentage of parents of respectable character is somewhat higher than Mr. McDonald's estimate."[3] Analysis of fifty parents of the industrial school pupils are given. "In the fifty cases 648 summonses were served—an average of 13 summonses for each person—43 warrants were issued and 94 commitments to prison made out. Of the 94 commitments to prison only 7 were actually imprisoned: 1 served six terms; 1 five terms; 2 three terms, and 1 of them one term of imprisonment."[4] These statistics are valuable as far as they go, but an inquiry into the ancestry for two or three generations back would make them much more valuable in determining the relative influence of heredity and environment as the cause of wrongdoing .

Here, again, we come face to face with these important factors in the production of social defectives. What can be done to check the evils of bad heredity and bad environment? Should man but use the same intelligence in dealing with this question that he displays in the breeding of domestic cattle the question would be promptly solved, so far as heredity is concerned; but he will not—he never will. That sympathy which Mr. Sutherland calls a "natural morality" is opposed to it; the general recognition of "liberty" and man's "natural rights" will never permit it. Indeed, the right to marry, the right to procreate his kind, no matter what his misfortunes may be in the inheritance of a debased mind or body, is a right which society will not infringe until altruism becomes as firmly implanted in the human breast as egoism is now. When the whole race becomes so unselfish, so self-sacrificing, that even its degenerate members recognize the wrong they do to society in propagating their kind, and voluntarily give up this fundamental right, then will improvement by suppressing the birth of defectives be possible. Do you suggest that these be compensated by the state, for giving up their right to marry, that the state shall give them an equivalent in money? If you think such a scheme possible, it is quite likely you underestimate man's procreative desires.

A writer[5] describing the life of the southern mountaineer tells the following anecdote: "I saw a boy once, astride a steer which he had bridled with a rope, barefooted, with his yellow hair sticking from his crownless hat, and in the blubbering ecstacy over the fact that he was no longer under the humiliation of accepting $75 a year from the state. He had proven his sanity by answering one question. 'Do you work in the field?' asked the commissioner. 'Well, ef I didn't,' was the answer, 'thar wouldn't be no work done.' I have always feared, however, that there was another reason for his happiness than balm to his suffering pride. Relieved of the ban of idiocy, he had gained a privilege—unspeakably dear in the mountains—the privilege of matrimony."

A recent writer[6] suggests that the hereditary social defective be gently chloroformed into a more perfect world; but where will you stop? Who is wise enough to say that this is a bad specimen which must be destroyed root and branch, while this, his brother, is not quite so bad, and, therefore, shall live and propagate his kind? Some have advocated mutilation to make procreation impossible. Curiously enough, it is the male only which is to be treated thus. Why the unsexing of the

female for the same cause has not been advised by these writers is not apparent. However, this operation would undoubtedly be as strenuously opposed as death itself.

Not only is such radical legislation as that suggested above never likely to be enacted, but mild, conservative laws, looking to the prevention of fraud in making the marriage contract, are opposed, as we see in the proceedings of various state legislatures every year.

To curtail the production of defectives by actual destruction of those who are so unfortunate as to be born, by mutilation, or by harsh laws, seems, then, practically impossible; we shall act much more wisely if we turn our attention to improving the environment which is the wellspring of so much vicious humanity. Shall we kill the degenerate offspring of the alcoholic, and never lift our hands or voices against the thing which is producing the degeneracy? How much of the sum total of degeneracy would be abolished by the abolition of alcoholic beverages? The question is not easy to answer; but it is entirely safe to say that alcohol is responsible for more degeneracy than all other causes combined.

Speaking again of the parents of pupils in the reformatory schools in England, Morrison[7] says: "As a rule parents who go to prison are hopeless drunkards; the remainder escape by payment of the fines. A large number of the parents are engaged in highly paid employments; in many cases it is not poverty which hinders them from fulfilling their parental duties, it is simply vicious habits of life. At the very least eighty of every hundred of them are addicted to vicious if not criminal, habits; the children came into the world in a polluted moral atmosphere, they are contaminated from the very earliest infancy without being aware of it; and, although their status is normal as far as the number of their parents is concerned, it is in the highest degree abnormal when the character of these parents is taken into consideration."

McKim[8] quotes as follows: "Of all hereditary taints, alcoholism is undeniably the most frequent and among criminals it is found almost always alone or in connection with other taints. It is the most common cause of degeneracy, and our prisons are peopled mostly with degenerates or with the children of drunkards. When in the ancestry of any criminal we can not find insanity, or epilepsy, or hysteria, we shall find nine times out of ten that alcohol has been the cause of all the trouble. The other taints may often skip a generation, but this is rarely the case with alcoholism. Alcohol is a poison that pardons not."

But what need to pile up evidence to prove the responsibility of alcohol as the chief factor in the production of degeneracy? The evidence is endless. It may be found on every hand. Look to the defective individuals in your own neighborhood; are they not the children of alcoholic parents, of an alcoholic father, at least? The one imbecile in my own vicinity is the son of a one-time alcoholic father. His coming cured the father of his vicious appetite; but what a price to pay! A young woman who has two score of babies to care for in a kindergarten tells me of a case of alcoholic stupidity in the person of a little lad, the offspring of a beer-drunken father and mother. He sits for hours, seeing nothing, doing nothing, apparently conscious of nothing. She has as yet been unable to arouse him to any kind of activity. This young woman was one of a class to listen to a few talks on the subject of exhaustion in children; and the keen interest she takes in this subject of inherited weakness in the children of alcoholics shows how much good could be accomplished by giving instructions of this kind to teachers.

Start wheresoever you will in the study of this subject of dealing with the hereditary criminal, with the incorrigible, with the defective of society, and when the evidence is all in, the overwhelming responsibility of alcohol stands out as the greatest, most important factor of degeneracy. If you are honest with yourself, no matter what your personal prejudices may be, you will accept this conclusion, for the evidence warrants it. The fight against degeneracy is a fight against alcohol; for let us remove this cause, because it is the most tangible and can be removed if we but will do so, and we shall see that our work is well towards completion.

Where the child is uncontaminated by heredity, viciousness is easily cured. A simple removal from evil surroundings is all that is needed to make good instruction immediately effective. Let the child be well fed; let him be properly clothed; let him have an abundance of room to move about, preferably a large field with forest, lake and stream near by, insuring an abundance of fresh air and exercise. Are not these ideal conditions for a proper education? Let the teacher, in co-operation with parent or guardian and physician, determine through what avenue the child's brain may best be reached to begin cell development, and let that avenue be chosen as the most available to reach the highest degree of development, the most useful education of which he is capable. When the degree of faulty development is such that it is not proper or profitable to deal with him in company with his more normal fellows, the child should be removed to an institution whose particular function is the education of defectives of his class. It is only with those who are faulty in a minor degree that we speak here; those who give much trouble accomplish little in the common schools, and are liable to become criminal in more mature years from lack of proper handling in the common schools. Let the school be a real "brain conditioning house," and do not urge the boy, do not irritate him with the, to him, detestable intricacies of Latin grammar, if he has a love for chemical experiments, for planting things and watching them grow, or for making things with saw and plane; do not blight his love for the free outdoor life of a herdsman or a farmer, to make a poor lawyer or a worse minister. Let there be teachers enough to give the pupils individual attention, and let the teachers be wise enough to see all the differences in the characters developed. No teacher can properly supervise the instruction of more than ten pupils. It is poor economy to put fifty or sixty or more pupils under the care of a single instructor. Their characters will never be known; their hopes, their aims, their ambitions, their secret desires, the knowledge of which is so important to insure the best results—the knowledge, indeed, of which is so absolutely necessary if the school is to be in fact a "brain conditioning house"—can not be known to him. Moreover, the instructor should constantly have in mind the child's heredity, what has been the mental and physical bias of his ancestors, and this he can not do when he has half a hundred or more to deal with. Nor is it possible for him to impress his own individuality upon so many. What the teacher actually is, what the pupils know him to be, what his ideals are and how closely he lives up to them, are matters of prime importance to pupils in this their imitative age; but the teacher's personality loses its force in direct ratio to the number among which it is distributed.

While the utmost freedom should be granted to defectives at school, they should nevertheless be held strictly accountable for their conduct. Less, very much less, should be forgiven in their conduct than in the con-

duct of the normal child. There is, on the contrary, a disposition in society to regard the offenses of these not as faults, but as symptoms of disease, to be condoned and forgiven on the ground of hereditary lack of self-control. Nothing could be more mischievous. One of the first things one of this class needs to learn, is that because of this lack of self-control he must be the more careful to avoid all occasion for giving offense through committing a wrong act. Once let him understand that he is regarded as the unfortunate victim of circumstances, and he will cast all self-control and efforts at self-control to the winds at once, yielding wholly to his vicious impulses. A youth of this kind under the author's care for a number of months improved in his conduct as soon as he was given to understand that he would be held strictly accountable for what he did. He had an alcoholic relative whose irresponsibility he had often heard asserted by a medical man, and drew the natural inference that when he, too, did wrong it was the disease and not himself that was at fault.

CONCLUSIONS.

Finally, the writer wishes to say a few words for the sake of emphasizing some of the propositions stated in this paper. They are these: Education is not merely the imprinting, the photographing of ideas upon the cells of the brain; it is a definite, biologic process, attended by development of the cells in a tangible way, the increasing of their bulk, the increasing of the number, length and complexity of their dendritic fibers, and that the brain which has the most cells thus developed, in all of its parts, belongs to the best, most widely educated individual. Man is born with many millions of cells which never become educated, which remain in the embryonic state, without axis cylinder and without dendrites. Certain individuals are born with deficient cell development, constituting them social defectives, degenerates, incorrigibles, criminals by heredity. The problem of reforming these is to bring about such cell development as will give them the normal individual's sense of right, the normal ethical sense, as will give them sufficient power to control their vicious impulses, and make proper conduct possible. The education of any group of cells leads to the development, though in a less degree, of all cells with which these come in contact; so that if the individual may be taught nothing more than a few muscular movements, at first, those will assist him in obtaining a more general education.

Heredity is the most potent influence in determining the characteristics of the individual. Degenerate ancestors can not produce sound, healthy progeny. Next to heredity, environment is the most potent influence determining conduct; because man, especially in his youth, is imitative in the highest degree. Degenerative changes in the individual of one generation, caused by the habits of a vicious environment, are transmitted by heredity to the progeny of the subject of acquired degeneracy Here they become a permanent heritage. Removing lesser degenerates from a vicious environment may so far restore them to the normal condition as to eliminate the degeneracy in the course of generations.

As it is not likely that heredity will ever be controlled by society through legislative enactment or otherwise, all efforts at eliminating degeneracy must be directed through two channels—education and change of environment.

In education the value of physical training must be recognized as equally important with or more important than mental training. Indeed, physical training must be regarded as the sole avenue, in many cases, through which the undeveloped brain cells may be reached; and, under all circumstances, cell development, through coordinated muscular movements, should go hand in hand with development through purely psychic channels.

As alcohol is admitted, by all competent authorities, to be the cause of by far the greater part of degeneracy, incorrigibility, criminality, the first step toward eliminating these conditions should be directed against the drinking of alcoholic beverages. The ninety million gallons, or more, of alcohol consumed annually by the people of our country, destroys more brain cells, produces more defectives and criminals than many times all other causes combined.

DISCUSSION.

DR. WINFIELD S. HALL, Chicago—It has been clearly demonstrated in this country that the mental development can be very greatly modified through physical development. In the case of the more pronounced examples of arrested development both mind and body are involved. In all such cases a successful result is reached only through the avenue of physical development. Hence physical development is absolutely essential and, in fact, must precede mental development in all cases of arrested development. Even in a normal child I believe that physical development is an essential preliminary to the broadest and most liberal mental development. Statistics all over this country and England show that to be the case. Another point is the influence of alcoholic heredity on these degenerates. It has been shown that a vast majority of the degenerates are from parents one or both of whom are addicted to the use of alcoholic beverages. This has been shown over and over again in the work at the Elmira Institute. These two points are as firmly established on statistical bases as any two facts in the whole realm of statistics.

DR. H. S. DRAYTON, New York City—I think the term "degeneracy" covers a broad margin of defect. We go among those who have to do with the insane and find a great variety of opinion as to what constitutes insanity. So broad indeed is the margin in which unbalance of mind exists that most people—I do not include the present audience, of course—appear to have some of the elements of "degeneracy" in their organisms. Dana wrote a paper on the topic and said that the stigmata of degeneracy were very broadly distriouted. The Lombroso school describes some 30 or 40 somatic features that point to psychic defect. Should we try ourselves by these it strikes me that few of us would pass an examination. As to the influence of education on degeneracy it strikes me that experiments made in different institutions of this country and Europe tend to snow that scarcely any young person can be found who is not susceptible of improvement to a considerable degree. This fact was emphasized by an experiment made at the Perkins' Institution for the Blind near Boston when under the management of Dr. Samuel G. Howe. An assistant to Dr. Howe tried an experiment with an idiot—a boy so low in sense defect as to be called "the oyster." In whatever posture he was placed he would lie until moved. He seemed without sense or sensibility. The assistant, not knowing what was best to be done, sat down beside that wretched being and read Greek for some hours every day, his idea being to obtain if possible some expression of attention or interest. After reading in this way for some three months he stopped one day and turned away, when he heard a semi-grunt, the first indication of anything like attention. Later, the "thing" added a slight movement to the grunt. Dr. Howe was so gratified with the small result that he had the work

continued, and in the course of a year or two "the oyster" was actually trained to be of service to himself and the institution. The incident warrants us in not despairing of improving the state of average "degenerates."

DR. JAMES PUTNEY, Charleston—I have had some experience in the oversight of the people in our county workhouse, and on inquiring into the cause of the conditions I have very frequently learned that the parents or grandparents of the subjects were drunkards. Most of the fathers or grandfathers were drunkards and some of the mothers.

DR. MADDEN, in reply—Of great importance is the so-called "crossed education" in which Professor Scripture of Yale University has shown that teaching one hand to become dexterous, rapid and strong, a large percentage of the same kind of education is given to the other hand although it may not be used at all. Not only this, but if a certain number of muscular movements be carried out with the one hand we may instruct the other hand to this same work in 30 to 40 per cent. of the time required to instruct the first hand. It has been found too, that not only when one arm was exercised did it increase in size, but also the other arm increased in size although it was not exercised. I believe we come nearer to appreciating what an education is when we look at it from a biological standpoint and we say that giving an education consists in developing the nerve cells, giving to them axis cylinders and dendrites, and the more dendrites the better the education, from the biologist's standpoint.

As to what is degeneracy, I think the word is very much overworked. When a man ceases to act in harmony with his environment and his conduct is not in accordance with the best interests of society, and does this through some defect in his nervous organization, especially if the fault is congenital, he is termed a degenerate. Our living in the midst of an evil environment may be constantly acting out of harmony with it in doing good. Of course, such a one would not be called a degenerate. One inheriting a vast fortune might be possessed with an altruistic notion that it was his duty to give it away, and in its disposal he might exhibit many eccentricities; still he would hardly be called a degenerate, so long as his acts contributed to the happiness of others. In spite of the fact that he might show an abnormal nervous make-up, it is very likely that he would be called a philanthropist. If a beggar applying to such a philanthropist for alms, in being refused should knock the eccentric philanthropist down, the latter would stand a chance of being called a degenerate. It is not so easy to define a degenerate; we recognize him much easier than we define him.

THERAPEUTIC INDICATIONS SUGGESTED BY THE CONDITION OF THE BLOOD.*

O. T. OSBORNE, M.A., M.D.

Professor of Materia Medica and Therapeutics at Yale University.

NEW HAVEN, CONN.

We are in the age when a better understanding of pathology and bacteriology has shown the absurdity of many pseudospecifics and of symptomatic treatment. We realize more and more the "phusis" of Hippocrates, the "archeus" of Paracelsus, the "pneuma" of Hoffmann, the "anima" of Stahl, and the "vis medicatrix naturæ" of later writers, which power Hahnemann so well demonstrated with his multiple dilutions of nothing, allowing disease to recover without interference. Also, we recognize the uselessness of attempting to cure or even to stay organic disintegration or obliteration.

While acknowledging the above, I think we have become too pessimistic therapeutically, and while we are directing our energies and remedial agents to the etiology and pathology of disease, we have forgotten to better, or correct, or aid the normal metabolism of the body.

Too many books on practice and too many teachers instruct carefully in the etiology, pathology, symptomatology, diagnosis, and prognosis of a disease and then briefly delineate a specific treatment, or say there is no treatment of any avail. The student thus learns to treat the disease by name only and does not treat the disease plus the individual who has it. Thus it is that many an unscientific practitioner of to-day, treating the patient and not making or caring to know the diagnosis in a doubtful case, continues to be in as great or greater demand than the physician who carefully makes the diagnosis, scientifically treats the disease, but forgets the man who has the disease.

Rather than ramble over the list of functions of the whole man, I propose to limit my remarks to a consideration of the blood, believing that in it may lie the wavering balance as to whether the patient survives or succumbs to a disease.

We can not properly treat any diseased organ or disturbed function unless we first know the physiology of that organ, and then the pathology of the disease or condition, the symptoms and signs showing us the degree to which this pathology has extended and giving us the prognosis for our treatment. Next, we must know the etiology to remove it if we can. The plan of treatment thus reached is rational and scientific, but in initiating it and carrying out such treatment it will often not be successful and will rarely be Asclepiades' *"tuto, cito, et jecunde curare"* unless it is modified to fit the man himself.

I trust I may be pardoned if for a moment I speak of the physiology of the blood. The gross constituents of the blood, viz., the plasma and its contained gases, the red corpuscles and the white corpuscles, have normally a certain slightly variable relationship to each other, and how easy it is for this relationship to become abnormal and react to the disadvantage of the whole life process.

While the specific gravity of the blood has a wide range of from 1040 to 1070, variations beyond these limits may have a wider significance and influence than we have previously considered. A much more variable property of the blood is its alkalinity, which is so readily increased by food and so constantly lessened by muscular exertion.

The range of from four to five millions of red blood corpuscles per cubic millimeter varies physiologically with the nutrition, the manner of life, and with age. The physiological diminution after meals is probably due to the destruction of the red corpuscles for the production of the bile pigment, while the decreased number of red cells in females during menstruation is probably due to the direct loss.

In normal conditions transportation to a more rarefied atmosphere will increase the number of red cells, showing that there is a surplus of red cells lying somewhere ready to be poured into the blood stream if there is a demand for them.

Studying the red corpuscles from a clinical and a diagnostic standpoint, we must take into consideration the osmosis that takes place through the stroma of the red cell, as we know that when they are large and well rounded the blood plasma is of low specific gravity. On the contrary, if these cells are shriveled and crenated we know that the plasma is concentrated and of high specific gravity. A large number of nucleated red blood corpuscles, except in embryonic life, shows that there is

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S Davis, Jr.

something wrong with the early life of the corpuscle, it not having completed its usual cycle to maturity.

Ninety-five per cent. of the contents of the red corpuscle is hemoglobin, which is a very unstable compound, being readily set free by bile acids circulating in the blood, or by poisons such as potassium chlorate. The coloring matter thus set free circulates in the plasma and is deposited in the organs or passes off by the urine. Many disturbances of the system as well as poisons may set free this hemoglobin. This is, of course, notably true in profound malaria.

Only 4 per cent. of this hemoglobin is hematin, and in this hematin is found the iron which is the element c oxygen and carbonic acid exchange. This constant change seems to do no injury to the blood corpuscles, but as the hemoglobin is the origin of the bile pigment and as bile is constantly present, the red cells must constantly die or be destroyed, hence new corpuscles must be formed. Though the average life of a corpuscle is not known, it is estimated by some authorities as fourteen days.

The principal origin of the red corpuscles in the adult seems to be the red bone marrow, and it is interesting to note that after severe hemorrhage the nucleated corpuscles of the bone marrow are increased in number and many appear in the blood stream.

The spleen, which may be an originator of red cells before birth, certainly becomes a reservoir for them during life, and under requirements of the blood may give up some of this reserve supply to the blood stream.

How the red corpuscles meet their death or are disintegrated for bile pigment products is not quite known, but physiologists tell us the histology of the spleen is admirably adapted for storing red corpuscles, and here they are probably principally destroyed, the splenic vein always containing more hemoglobin than is found in any other part of the circulation. This hemoglobin is then taken by the blood stream directly to the liver and is there manufactured into bile pigments.

So much for the physiology, as far as we now know it, of the red blood cell. Now, what do we know of the white corpuscles? Under the microscope we find various types of white blood cells, the simplest classification of which is into the following: 1, lymphocytes, which are similar to the cells found in the lymph glands, contain nuclei, and are not capable of ameboid movements; 2, the mononuclear leucocytes, which are large corpuscles and have ameboid movements; 3, the transitional leucocytes, which are the transitional stage of the mononuclear to the polynuclear leucocytes, and 4, the polymorphous or multinucleated leucocytes, which are large corpuscles with several nuclei and very active ameboid movements.[1]

It seems clear that the mononuclear leucocyte develops into the polymorphous leucocyte, but whether the lymphocyte is an earlier stage of the mononuclear leucocyte is not known. It seems proved that the lymphocytes develop in the lymph glands and lymph follicles in the so-called germ centers of adenoid tissue that multiply by karyokinesis and are then poured out into the blood plasma.

Huber[2] thinks that the leucocytes may have various origins, which he separates by the staining properties of the granules, the neutrophile developing in the blood from mononuclear leucocytes, which have their origin in the spleen or bone marrow. The eosinophile leucocytes he thinks in all probability come from mononuclear cells which are found in the bone marrow, and they may also develop from connective tissue, while the leucocytes with the basophile granules, he says, probably enter the circulation from the connective tissue of certain regions.

The duties of these leucocytes seem to be first to protect the body from pathogenic bacteria by phagocytosis, while Howell[3] says that the lymphocytes seem to aid in the intestine in the absorption of peptones and fats.

We know little or nothing of the life history of these cells, but believe that as they normally disintegrate, they probably furnish some proteid material to the blood. We know little or nothing of the diminished number of white cells, but we do know something of an increased number, or leucocytosis, by which term we mean a temporary increase in the number of white cells. This temporary increase normally occurs after each meal at the very time when the red cells are less in number, the red cells perhaps disintegrating to form more bile while the white cells are poured out to aid in the absorption of the nutriment. Anything that irritates or stimulates the lymph glands must increase the number of white corpuscles in the blood.

We have not paid enough attention to the blood plasma or to the possibility of its being modified in disease, especially in anemias. When we consider the variations of the red blood corpuscles under the microscope caused by differences in the density of the surrounding fluid, we realize how very important in many cases a knowledge of the character of the plasma would be. When we study the physics of osmosis and the physiologic action of absorption and excretion, we should also consider the character of the blood plasma. Chemistry shows us that through an animal membrane there will be an exchange of solutions if the osmotic pressure of the two fluids is dissimilar; the salt, more or less slowly, depending upon its character, will pass from the stronger solution into the weaker, and water will pass from the weaker into the stronger until the osmotic equilibrium is established, at which time the solutions are said to be isotonic. Certain membranes of the body, notably true of the intestines, allow water to pass through freely by this osmotic force, but will retain the salts until an equilibrium is established. Again, we find that membranes may be permeable to one salt and not to another, these salts, then, having slow absorption. Such is true of the cathartic salts in the intestine, which tend to cause osmosis of water and are very slowly absorbed and hence produce watery purging.

We have not time to consider the elements of the blood plasma, but it may be noted that calcium salts in the blood favor coagulation, possibly a clinical indication for calcium in bleeders and the blood plaques or platelets seem to have to do with the coagulation of the blood.[2]

The variations in the character of the plasma must cause variations in the rapidity with which certain fluids or salts may be absorbed, or possibly may affect the absorption of the nutritive products of digestion, and hence there can be such a condition of the plasma that it can not absorb the materials or salts which are necessary for the growth of the cells and the nutrition of the body. Here we come to the question as to why, when there is sufficient iron in the food it may not in certain cases be absorbed, as in chlorosis.

My reason for this discussion would not be evident if I did not speak for a moment of the physics of the

1. Huber's Histology, p. 173.
2. Ibid., p. 176.
3. American Text-Book of Physiology.

blood and therefore the importance of the consideration of the blood in its totality as well as in its component parts.

A normal adult has one-thirteenth of his body weight in blood; in other words, a man weighing 170 pounds should have 13 pounds of blood. This proportion, of course, is not true in the obese and is not true in children. We undoubtedly generally forget that, roughly speaking, from nine to fifteen pounds of the adult weight is constantly in motion, and while I do not wish to revert to the English and Italian physical medicine of the 17th century, we should perhaps recognize the force that it takes to move this weight and how important it is in weak conditions for the individual to be in a horizontal position and not be compelled to propel the whole of this weight against the force of gravity.

At any given time one-fourth of this blood is in the heart and larger blood vessels, one-fourth in the liver, one-fourth in the muscles, and the remaining fourth is distributed among the various internal glands and organs. In hyperemia of the brain or internal congestions, we undoubtedly have a disturbance of this normal distribution of the blood, which by various well-recognized physical methods we more or less successfully bring back to the normal condition. I also venture to say that there can undoubtedly be too much blood at the surface of the body giving a feeling of warmth to the skin, as in some neurotic women. These patients always complain of heat, and probably have a diminished amount of blood in the glands and digestive organs, and hence their imperfect nutrition.

We are now in the age of a better understanding of the vasomotor system and recognize the opening and shutting of the arterioles and the consequent flooding or anemia of the capillaries as a very important element, not only in diseased conditions, but in the normal welfare of the individual. When we consider that we can cause anemia of the brain by hot sitz-baths, and that even slight irritations of the stomach, or intestines can cause dilatation of the abdominal vessels, which vessels can hold all the blood of the body if they become paralyzed; when we know that we can cause serious cerebral congestion by cold baths and chilling of the body; when we know that we can cause peripheral anemia enough to produce gangrene with continuous large doses of ergot, and that with nitro-glycerin we can cause sufficient dilatation of the blood vessels to produce anemia of the brain and fainting, we have a power presented to us which I do not think we sufficiently consider or sufficiently utilize to the advantage of our patients.

In the first place we are not careful enough in fever processes to keep the blood at the surface of the body where it cools and keeps down the temperature, and therefore saves the waste which high temperature will cause. We have all seen a profuse early sweat abort or prevent the chill in a malarial paroxysm when we have had no time for previous curative treatment. This, of course, simply means the dilatation of the surface blood vessels, thus preventing the chilling and the consequent internal congestions.

The condition of vasomotor ataxia plays an important part in many functional disorders, notably true in neurotics and neurasthenics. When the blood should be at the surface, the surface vessels are contracted and there is too much blood in the internal organs, perhaps notably the brain, as at night, causing insomnia; when there should be anemia of the surface, there is a flushing of the skin in these cases, giving sleepiness in the daytime and perhaps an imperfect digestion, constipation, and other functional disturbances. This condition of vasomotor ataxia seems to be present in marked degrees in most cases of hysteria.

In considering these displacements of the blood we come to the study of the cause of contraction and dilatation and find that the principal vasomotor center is in the medulla oblongata, which, as well as the peripheral vessels, is readily stimulated by various substances. In the normal individual the thyroid gland seems to furnish a vasodilator, while the suprarenals furnish a vasocontractor element. Possibly these two secretions regulate the peripheral vasomotor system. If either of these functions is disturbed we have varying symptoms, depending upon which one is in predominance. I feel firmly convinced that it is not at all necessary to have a developed Graves' thyroid disease for us to have an increased secretion of the thyroid. I believe that neurotics and possibly hysterical cases have an increased secretion from this gland, and that various of our functional disturbances, such as palpitation, cerebral irritability, insomnia, sweating, nervousness, hot flashes, muscular weakness due to lack of blood-vessel tone, can be due and is due to this increased secretion.

On the other hand, I feel that continued high tension of the arteries, with the consequent chronic endarteritis, gouty and atheromatous conditions, can be due in later life to the diminution of the thyroid secretion and the predominance of the suprarenal secretion, causing the contraction of the peripheral blood vessels.

In the condition of persistent vasodilatation, due, as I think, to hypersecretion of the thyroid, we should spend a great deal of care in toning up the peripheral blood vessels by teaching them to open and shut, by various cold water applications, douches and sprays, and insisting upon a quiet mental as well as physical life to prevent the pounding of the heart weakening these dilated blood vessels. Massage and graduated physical exercises will increase the muscle-tone, which will contract the blood vessels of the muscles, which vessels contain one-fourth of the body's blood.

On the other hand, in the condition of too-high tension of the blood vessels, our aim should be to relax, and I trust I will not be accused of going back to the Methodists in the first century when I say these conditions need such treatment as will relax the blood vessels and increase elimination. Too high tension calls for exercise, warm baths, free catharsis to reduce the amount of fluid so that the tension will not be as great, dilatation with small doses of thyroid gland daily, nitroglycerin in small doses, as 1/400 three times a day, or small doses of chloral.

So much for the gross chronic conditions, but how much more carefully we ought to watch the condition of the blood vessels and the surface of the body in acute conditions in which the blood or life-power of the patient is endeavoring to correct the pathology present.

Why try to make a patient sleep with some hypnotic when strychnia is being given, when the omission of the evening dose of strychnia may be sufficient? Why continue to push alcohol, a vasodilator, when the patient is failing from peripheral collapse? Why impede the activity of the phagocytes with large doses of quinin in infections that normally produce leucocytosis? Now, let us return to the finer details of the blood in the different conditions.

1. *Plasma.*—This can be either increased or diminished in amount. Briefly, the cause of the diminution

may be hemorrhage, profuse watery diarrhea from any cause, profuse sweating, as seen in the prostration from pilocarpin, or profuse diuresis, as seen in diabetes. It may be relatively diminished in amount in conditions of shock and collapse, where there is a vasomotor paralysis, and may be relatively diminished in conditions of chronic vasodilatation, as occurs in Graves' thyroid disease, where there is too much secretion of vaso-dilating stuff, and in Addison's disease, where there is probably diminished secretion of vasocontracting stuff.

The symptoms of acute hemorrhage we well recognize, but perhaps we do not consider that the symptoms of the diminished amount of plasma from all these causes will always be the same, viz., low blood pressure due to imperfect filling of the vessels; poor heart action, it becoming rapid and irritable, due to the imperfect filling of its cavities, and from the diminished pressure, imperfect nutrition through its coronary arteries; thirst due to the demand for more fluid to fill up the blood vessels; more or less dyspnea due to the impaired circulation; cerebral excitement perhaps soon followed by sleepiness due to anemia of the brain. The skin is moist and cool when the plasma is rapidly diminished, but it may become dry and harsh and even shriveled in chronic loss of plasma, as in diabetes.

In any of the acute conditions in which this diminished amount of plasma occurs the indications for treatment are always the same, viz., to stop further loss, to transfuse in serious conditions, in any method which seems best, the normal saline solution. In less serious conditions to give plenty of warm, non-irritant fluids either by the stomach or perhaps better by the large intestine, and then to contract the peripheral vessels and thus relatively increase the amount of plasma either by strychnin, atropin, or digitalin hypodermically as we should not forget that in these conditions of diminished blood pressure the stomach does not absorb drugs with readiness, if at all. I reiterate that whatever be the cause, or whatever be the condition treated, or whatever be the acute or chronic, inflammatory or organic process, if this condition of diminished plasma occurs, these symptoms will develop, and the treatment is that of th condition of diminished plasma plus whatever treatment the causative disease calls for.

The plasma is increased in amount in conditions of simple plethora where there is diminished excretion as in uremia, and relatively in chronically contracted blood vessels, as in arteriosclerosis and gout. The symptoms are high tension; flushed face; more or less dyspnea due to congested pulmonary circulation; slow heart, due to the increased peripheral resistance; digestive disturbances, due to a congested portal circulation, which predisposes to the formation of biliary calculi.

When for any reason we have diminished excretion or a contracted state of the blood vessels, these symptoms will supervene, and whatever the treatment is for the condition causing it, we must also treat this increased amount of plasma by increasing elimination, dilating the peripheral blood vessels, and diminishing the ingestion of food.

Very probably the plasma has its specific gravity diminished in anemia and in impaired alimentary absorption, giving the tendency to hemorrhages and to edemas. We already treat this condition sensibly by increasing the excretion from the bowels by proper laxatives, correcting any alimentary disturbance that is present, and contracting the blood vessels with digitalis.

The specific gravity of the plasma is probably increased in gout; hence the tendency to urate deposits in the joints and other parts of the body, and the tendency to the formation of urinary calculi. The treatment of this condition is a modification of the food ingested, with the intake of large quantities of water medicated in any way that may seem best, and the adoption of any measures that promote the peripheral circulation, dilate the vessels generally and prevent them from being so permanently contracted that they will not absorb more water and thus dilute the plasma.

2. *Red Blood Corpuscles.*—These are perhaps never increased sufficiently to cause comment. They may be normal in number, but useless for oxygen exchange after certain poisons have been received into the system, such as potassium chlorate, carbonic oxid gas, and perhaps in chronic malarial poisoning. In this condition the corpuscles so affected are useless to the metabolism. Any method that will hasten their discharge from the system and encourage the formation of new corpuscles, would be good treatment. Hence in certain cases, perhaps, it is advisable to do venesection and then infuse salt solution.

Our greatest interest in red corpuscles, of course, lies in their diminution. They are diminished, and our patient is anemic, as we call it, in the various anemias, chlorosis, in chronic impairment of any function, and in acute disease, especially in acute infections. We can have an acute loss of red blood corpuscles, of course, from hemorrhage, but I wish to emphasize the fact of the acute loss in malignant infections, which cases dying suddenly with symptoms of acute anemia I have termed *medical shock*. The treatment of chlorosis due to impaired alimentary chemistry, and of essential anemia due to the migration of the colon bacillus, according to Adami, it is unnecessary to discuss, but I do not think we are careful enough to give treatment to promote the formation of red blood corpuscles during acute feverish processes, especially when due to infection.

We have long recognized the advantage in diphtheria of giving iron, and it has been lauded in erysipelas, but I wish to state my belief that every case of typhoid fever will do better with the tincture of the chlorid of iron than without it.

Whether or not the blood corpuscles are themselves occasionally attacked by germs other than malarial as seems to occur in malignant infections, any fever that is prolonged any length of time, by interfering with nutrition, will impair the output of red blood corpuscles, and our patients will weather these acute conditions better. come out of them less prostrated, have less anemia, and shorter convalescence by giving the tincture of the chlorid of iron during the acute process. We not only furnish a stimulant to the blood-forming organs perhaps, but we add hydrochloric acid to the stomach when the amount is normally diminished.

3. *White Corpuscles.*—These perhaps are never diminished except relatively at such times as perhaps when a normal leucocytosis should be present. When they are chronically increased in number, we have the condition of leukemia, which condition, though at first functional, we as yet are utterly unable to stay. We have not yet discovered drugs or any treatment that will diminish the secretion of an internal gland, or will stop the output of white blood corpuscles.

The white corpuscles are increased daily, physiologically, as previously stated, for phagocytic work in infections of all kinds. The infections that typically cause a large amount of leucocytosis are those which

cause associated glandular swellings. These are typically diphtheria, erysipelas, scarlet fever, and septicemia. We also find some leucocytosis in rheumatic fever, cerebrospinal meningitis, and occasionally in typhoid fever. In acute tuberculosis and in chronic tuberculosis, leucocytosis does not occur unless there are some dammed-up pus formations. In pneumonia the leucocytosis may reach an excessive amount, disappearing gradually after the crisis, and the prognosis is often based upon the amount of leucocytosis.

These leucocytes must be like the armies of a nation, there being a standing army for police duty, and perhaps there is always military law for all invading bacteria, but in rapid attacks of virulent bacteria a reserve army can be called out or produced, and perhaps, if necessary, there is also a second reserve.

Bacteriological study having showed this leucocytosis in infections to be protective, is it perhaps not our duty in such conditions to promote this condition? Hence, perhaps the nucleins or thymus gland preparations should be given in all acute infections, as diphtheria, scarlet fever, typhoid fever, pneumonia, and perhaps tuberculosis.

In the period of convalescence from any acute disease we find a condition of vasomotor ataxia. The patients are hot when they ought to be cold, cold when they ought to be hot, sleepy when they should be awake, awake when they should be asleep. The least indiscretion of food causes internal disturbance and congestions, the same lack of blood-vessel tone is perhaps the cause of the obstinate constipation, not enough fluid being excreted into the intestine or too much of the fluid in the intestine being absorbed. The least cerebral excitement causes a rise of fever, showing that the vasomotor regulation of heat loss and heat production is badly managed, in other words, a vasomotor ataxia exists. Anything that educates the peripheral vessels to again react normally, such as massage, electricity, gentle exercise, sponging, and baths will improve all of these conditions which, though multiple in manifestations, are due to but a single cause, i. e., vasomotor ataxia.

I fear this paper will be considered erratic, but perhaps it will stimulate more consideration of the general condition of our patients while we are scientifically treating the etiology and pathology of the disease present.

TREATMENT OF NEURASTHENIA.*

HAROLD N. MOYER, M.D.

CHICAGO.

In inviting your attention to a brief consideration of the treatment of this disease, I do not hope to present anything especially new, with the possible exception of the application of prolonged cold, the marked beneficial effects of which I have noted in two patients.

Everything in the treatment of neurasthenia depends upon the diagnosis. In too many instances the conception of neurasthenia in the physician's mind is very like that which obtains in hysteria, namely, that it is a term which is to be applied to any anomalous symptom for which there is no other explanation. Again, many practitioners do not clearly differentiate between hysteria, neurasthenia and hypochondria, grouping them all together under the first or second of these terms. To be sure, they all belong to the functional nervous group, but the treatment of these different conditions varies greatly, and the successful handling of an individual case depends largely upon the fundamental distinctions in these three conditions. Rest, which is imperatively indicated in neurasthenia, is certainly disadvantageous in many of the milder forms of hysteria. In hypochondria we are dealing with a pure psychosis, in which the patient has delusions, or imperfect conceptions regarding his health. The treatment for the most part that would be applicable in neurasthenia and hysteria is not appropriate for an hypochondriac.

To my mind, the central point in the diagnosis of neurasthenia is the presence of the fatigue symptom; without this I can not understand a diagnosis of neurasthenia. The fatigue symptom is difficult of definition. It consists essentially of fatigue upon exertion, which ordinarily, in a well person, would cause no such sensation. This may vary from a condition so severe that even two or three movements of the arms, such as bringing them up to the head, will cause such extreme fatigue as to incapacitate the patient for making another movement with the upper extremities, to such a slight decrease in the capacity for exertion as to be scarcely noticeable. It would be as improper to make a diagnosis of neurasthenia without this fatigue symptom as it would be to speak of a case of chorea without the characteristic disorderly movements.

The portion of the body in which the patient experiences the greatest amount of fatigue has given rise to special division of neurasthenia, such as spinal, sexual, psychical, etc. Such divisions are quite useless, as a close analysis in most cases will reveal the general character of the symptoms, a certain few of them only being accentuated by the patient. The latter's subjective statements ought not to furnish a basis for classification. The fatigue symptom may involve the sensory side of the nervous system as well as the motor; a certain mental incapacity is usually complained of, in some very markedly, so that they will come to consult you to learn whether they are becoming insane. A very common statement among these patients is that they are suffering from failing memory. A very brief conversation with them develops the fact that they have mistaken a failure of attention for a failure of memory. They will read something, and an hour afterward will recall the fact of the reading, and, to their surprise, they are not able to recollect the subject matter. They at once jump to the conclusion that this is loss of memory, while in fact there was merely a want of attention while they were reading. This is startlingly impressed upon their minds, and many of them can distinctly recall a number of instances of that kind extending over weeks. A graphic description of this mental state is to say that such patients "remember that they have forgotten." It is evident that this is very different from the true loss of memory, such as we have in the organic affections of the brain.

Another distinguishing symptom in neurasthenia is that the pains which are spoken of as such by the patient are in reality a sense of distress or discomfort—sometimes graphically spoken of as a misery, rather than a pain. In part, they are the outgrowth of the fatigue symptom, especially the pains in the back, which are due to the extraordinary use to which the back muscles are put in maintaining the upright position.

Neurasthenia is to be distinguished from hysteria by the absence of anesthesia, a failure of the inversion of the color perception of the retina and a want of the pe-

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

culiar psychical manifestations of hysteria. There is some similarity in the morbid introspection of neurasthenia and hysteria, but, as a rule, the peculiar characteristics of hysteria are readily distinguished from those of neurasthenia. In hypochondria the purely delusive character of the malady is easily differentiated from the underlying nerve weakness which is characteristic in neurasthenia. The neurasthenic always has a tendency to exaggerate his symptoms, but they are not cut out of the whole cloth as they are in hypochondria.

The term "essential neurasthenia" has been employed to distinguish the primary form of the disease, and that is the sort of neurasthenia of which we shall speak in our remarks upon treatment. Every case of convalescence from an infectious disease is really one of mild neurasthenia, and many of the symptoms which attend constitutional diseases and the chronic infections, such as tuberculosis, are clearly neurasthenic in character. I do not call such cases neurasthenia; hence, the diagnosis depends upon the exclusion of underlying constitutional states—anemia, chlorosis, tuberculosis, inflammations of the gastro-intestinal tract, etc. If such cases are rigidly excluded, it will be found that the number of primary neurasthenias is comparatively small; but we must still recognize that such a primary weakness of the nervous system is possible without coexisting involvement of other organs, and in which the alteration in nutrition, which is almost always found in well-marked cases of neurasthenia, is secondary to the nervous involvement.

This close distinction between secondary and primary neurasthenia is vital from the standpoint of treatment. In the presence of an adequate cause, if that be not removed recovery will not take place.

Another variety of neurasthenia is the congenital form, to which the term neuropathy has been given. These patients are, so to speak, born tired, there being a congenital deficiency in the protoplasmic activity of the nerve cells. But little can be done with the congenital form of neurasthenia. It seems to be dependent upon a biochemic deficiency for which treatment will do nothing.

In the treatment of neurasthenia, therefore, we would refer to only two varieties: those in which the disease is acquired and those which are primary. The underlying defect is in all cases a nutritional disturbance. Many would refer these cases to uric acid diathesis, whatever may be meant by such a term. I have long since abandoned a treatment of functional troubles based upon a uricacidemia. I am confident that I can not recognize such a condition, and a treatment based upon such theoretical consideration has proven most fallacious in my hands. In those cases in which it was successful, the effect of the treatment could as well have been explained upon some other theory as that of an excess of uric acid in the blood.

At the beginning of the treatment of a case of neurasthenia, the most important thing is to obtain the full confidence of the patient. He should be told frankly that his condition is curable, and that his recovery depends largely upon himself; unless he will put himself absolutely under the direction of the physician for a period of from three to six months, it is better not to undertake the treatment of the case. If the patient will agree to a careful regulation of his habits and diet, then you may enter on the treatment with some hope of success. The simple diagnosis made in the office, followed by a prescription, without further directions to the patient, simply results in his drifting from physician to physician, without obtaining the slightest relief. The disease finally becomes chronic and fixed, or else there is that natural amelioration which usually takes place. In most of the acquired forms of neurasthenia, the clinical history shows a gradual invasion of the malady marked by an increase in the fatigue symptoms, which deepen for a period of months, sometimes approaching a year, and, at the end of that time, there is a gradual change for the better; hence, neurasthenia can be generally spoken of as a self-limited disease, having a natural tendency toward recovery even without treatment.

Next to obtaining the full control of these patients, it is of the utmost importance that persistent suggestion be employed—not hypnosis. The patient should be instructed to avoid, under all circumstances, talking over his ailments with any one excepting his physician. If he is asked about his health, he is to be instructed to make some indifferent reply, or to state that he is better. Under no circumstances is he to be allowed to discuss with any one of his symptoms, treatment or subjective state. This regulation relieves him somewhat from counter suggestions. The physician should then undertake a careful regulation of the life of the patient, making him keep a record of his sleep, food, appetite, bowel movements, baths and exercise. This should be looked over carefully by the physician twice, or at least once a week, and such corrections or additional directions given, as may be needed.

Rest is the sheet anchor in the treatment of neurasthenia. In the more severe cases we should employ the rest cure of Weir Mitchell; but we should remember that there are many hysterics and neuropaths who do very poorly, or, indeed, may be harmed by the rest treatment, even in a modified form. Neurasthenics, however, are all benefited by rest. In only severe cases, in which there is a profound disturbance of nutrition, should complete rest be employed, and, oddly, it is found to be more efficient with women than with men. As a rule, neurasthenia in men rarely requires the full rest treatment, but what I have elsewhere spoken of as a modified rest treatment may be employed with great advantage.

My patients are required to remain in bed many hours more than they have been in the habit of doing; they are directed to remain in bed until noon, and their hours at the office are sometimes restricted to two each day providing they can not avoid some direction of their business. As a rule, the rest which is prescribed is to be taken in a recumbent position. Frequently it is best that one of these patients should be enjoying some light exercise, preferably associated with mental diversion, or else be flat upon their backs. Either one of these is better than that the patient should spend his time moping around, as so many of them do.

In this connection I can not speak too highly of the value of golf in improving the nutrition of neurasthenics. It seems to furnish just the amount of exercise which they need, and, above all, it is taken in the open air. This improves the appetite, and the amount of exertion may be so carefully increased that there is never any strain upon the patient, and, as his nutrition improves, he gradually acquires an increased capacity for exertion. Any exercise that is ordered for the neurasthenic should always fall short of causing fatigue, no matter how slight the exertion may be.

Associated with the rest, the patient should be placed on a modified diet, which should invariably in neurasthenia without complications be a mixed one. Idiosyncrasies in the matter of diet are very common in neuras-

thenics; and should be carefully considered. Milk and eggs, where they are digested, will be found of special value. If milk does not agree with the patient, uusually mixtures of cream and water, or cream, water and milk, will be easily digested. As a rule, neurasthenics take too little water, so that they should be directed to take a glass of water at certain hours in the day; this will tend to relieve constipation. It is a singular thing that most neurasthenics have no proper sense of thirst.

Drugs, as a rule, are of little value in the treatment of neurasthenia. The judicious administration of strychnia is of some value. The patient feels the stimulating effect of the treatment, which produces a sense of well-being, and this produces a favorable mental state, so that its liberal administration in the first few weeks of the treatment is often useful. If it is given, it should be employed in large doses; a twentieth, or fifteenth, or even a twelfth of a grain is well borne by many of these patients. A few of them, however, can not take strychnia at all. Cannabis indica is a drug which is also of some value in producing a sense of comfort and well-being in the patient. It should not be continued for any length of time, and it, like strychnia, is probably dependent for its good action upon the effect which it has upon the mind of the patient. In cases of extreme agitation and failure to sleep, a few large doses of the bromids may be useful at the outset of the treatment.

Hydrotherapy in some form is exceedingly valuable, the most important being the application of a sheet wrung out of cold water each morning as the patient gets out of bed. If this is done promptly, and the patient vigorously rubbed after the application, producing a quick reaction, the benefit is very marked.

In two of my patients, during the past winter, I have had them exposed to an outdoor temperature for several hours at a time, following, in this, somewhat the plan that is now employed in the outdoor treatment of tuberculosis. In one case this was a modification introduced in the course of an ordinary rest cure, and I was astonished at the beneficial results. There was an immediate improvement in the appetite, the patient slept better, and the general effect on the nutrition was very pronounced. This exposure to cold was brought about by raising the windows, turning all the heat off in the room and carefully protecting the patient by heavy blankets and hot water bags in the bed. Another patient spent most of her time in the house and was under a modified rest cure. This patient was put on an open veranda, carefully protected from the weather. On several days the thermometer registered near the zero mark. The colder the days the greater was the benefit. This innovation in the ordinary rest cure treatment I believe to be of great value, but, of course, it is only applicable during the winter season.

Treatment of Sinusitis by Hydrotherapy.—Zangger states in a communication to the *Corr. Blatt.* of August 15, that acute catarrh of the frontal sinus, rebellious to medicinal measures, has been invariably relieved and cured in his experience by an energetic sweat bath. The profuse perspiration induced is followed by increased absorption on the part of the tissues and the catarrhal condition in the sinus is improved. He thinks that the same measure might be applicable in case of suppuration, and would apply it before resorting to surgical intervention. The sweat bath is repeated every other day for two to five times, as indicated by the symptoms. He has also obtained excellent results from it in pleuritis and tubercular adenitis.

A SIMPLE OPERATION FOR THE RADICAL TREATMENT OF HEMORRHOIDS.*

J. RAWSON PENNINGTON, M.D.
PROFESSOR RECTAL DISEASES, CHICAGO POLICLINIC.
CHICAGO.

Hemorrhoids are usually described as bluish-red vascular tumors occurring in the thickened mucous membrane of the anus. They are generally considered to be varicose dilatations of the hemorrhoidal vessels, brought about by obstruction to the blood current and by chronic inflammatory processes. According to the investigations of Reinbach,[1] however, a hemorrhoid is a true angioma, whose development, which may begin in early childhood, depends on a new formation and cavernous metamorphosis of the blood vessels, and may be quite independent of any obstruction to the blood flow.

As the pathology of hemorrhoids seems to be a more or less disputed question, and, since there is such a great variety of methods advocated for their treatment, which is probably due, in part at least, to the various conceptions of their pathology, I submitted to Dr. W. A. Evans specimens of these tumors for histologic and pathologic examination, hoping thereby to arrive at some definite

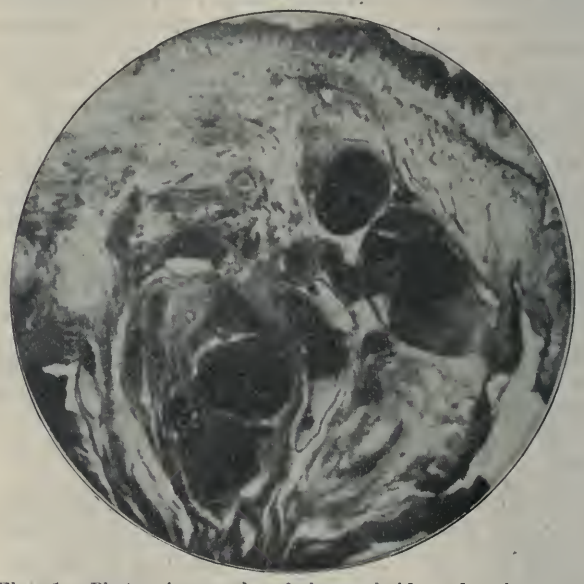

Fig. 1.—Photo-micrograph of hemorrhoid under low power, showing enlarged blood vessels and blood lakes.

conclusion as to the best means of treating this ailment. His report, together with the clinical observations which I had made, confirm, in a great measure, the pathology of this affliction as observed by Reinbach (Figs. 1 and 2). Hence, it seems that we should adopt or devise some method of operative procedure whereby we can remove the diseased structure—the angioma—and at the same time facilitate the reconstruction of the crippled mucosa and submucosa. That method is surely not to be found in the ligature, clamp and cautery, Whitehead's or many other operations I might mention.

In fact, it seems to me that it would be a physical impossibility to do a radical operation on a well-defined case of internal hemorrhoids by either the ligature or clamp and cautery, and, at the same time, preserve the contour of the anus. Furthermore, I should think that the same criticisms might be easily sustained with reference to the Whitehead operation, and also the method

1. Ziegler's Pathology, p. 323.

of excision as practiced by Allingham, as well as those methods of suturing where the hemorrhoid is seized with a pair of forceps, its apex cut off and the edges sewed together, as in Earl's operation. This procedure embodies the same principles and therefore is subject to the same criticism as that of the ligature or clamp and cautery method. Marcy's operation, where the hemorrhoidal mass is dissected, tied and cut off and the edges of the mucous membrane brought together with suture, is, from a theoretical standpoint, ideal, but its objections are: 1, the danger of suture infection; 2, painful swelling, and 3, hemorrhage and the formation of a blood clot at the site of the original hemorrhoid. Only recently a medical friend of mine came near losing his life from suture infection following this operation, and a few days ago one of our leading surgeons, Dr. Carl Beck, recited to me a case in which his patient had much edema and painful swelling following this method. Similar criticisms might be submitted with reference to the submucous ligation as practiced by Ricketts.

Consequently, after carefully studying all of the above methods and many more, it occurred to me that the most rational way of treating this condition would be by everting the pile-bearing area and removing an ellipse

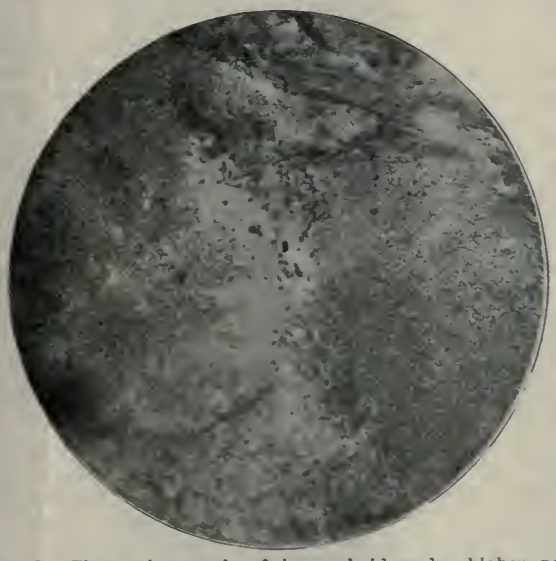

Fig. 2.—Photo-micrograph of hemorrhoid under higher power, showing blood lakes separated by thin wall of fibrous tissue and endothelial lining of blood vessels, only.

from the apex of each tumor commensurate with its size, then dissecting out the angioma, when the remaining walls of the tumor would collapse and, if the ellipse had been carefully and intelligently removed, would practically cover the denuded surface when the bowel was in a passive state. This gave rise to the origin of the method presently to be described, which seems to me the most rational of all methods for the radical treatment of this malady.

Given, for the purpose of illustration, a case of well-defined internal and external hemorrhoids. The second night before the operation administer from 2 to 5 grains of calomel in broken doses, in combination with subnitrate of bismuth and pepsin. The following morning give one-half ounce of Rochelle or Epsom salts. At 9 o'clock the night before the operation shave the anus and give a bath and a colonic flushing. At 7 o'clock the following morning give an enema of from one-half to one pint of cool water and operate two hours later. This method of preparation gives a clean field in which to operate.

The patient, being anesthetized with either a local or general anesthetic, is held upon the operating table in the lithotomy posture by means of a Clover crutch. The sphincter is then gently and carefully divulsed with the fingers, and the rectum irrigated with an antiseptic solution, usually bichlorid of mercury 1 to 3000, followed by normal salt solution. Each anal quadrant is now grasped at the muco-cutaneous junction with a pair of T forceps (Fig. 3). These are held by an assistant. By means of these instruments the anus is everted and the internal tumors exposed (Fig. 4). Now seizing

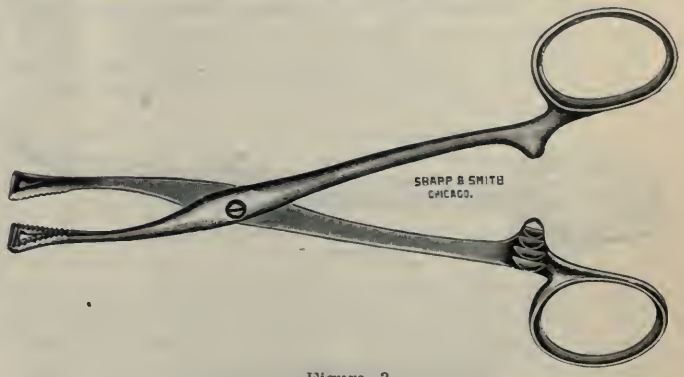

Figure 3.

with the full hand the forceps attached to the posterior quadrant, fully evert it, and with a pair of scissors sharply curved on the flat (Fig. 5) remove an ellipse from the apex of the hemorrhoid commensurate with the size of the tumor. This permits most of the blood in the tumor to escape. All of the angimatous tissue is now carefully removed, when the remaining wall collapses. This leaves a very small area, if any, of denuded surface (Fig. 6). Each quadrant in regular order is

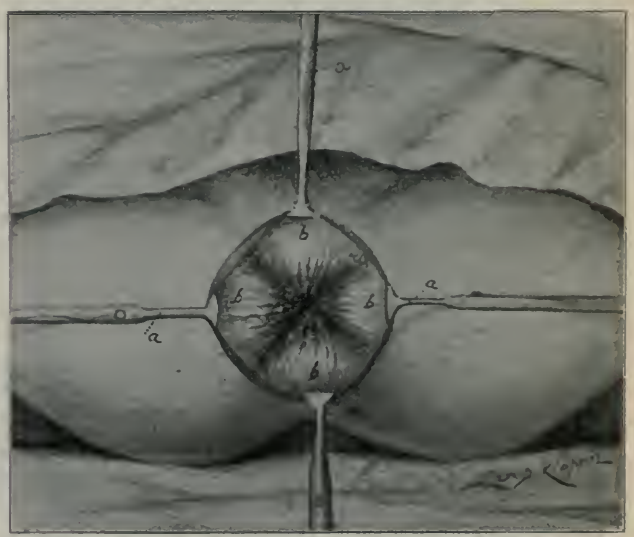

Fig. 4.—Diagrammatic; illustrating the application of the T forceps (*a*), to the muco-cutaneous junction and the exposure of the hemorrhoids (*b*).

treated in like manner. A stream of hot sterilized saline solution—115 to 125 F.—flows over the field continuously during the operation. Any spurting vessels are caught with a pair of forceps and thoroughly twisted. Should this fail to control the hemorrhage, throw a ligature around the vessel and ligate it; so far I have not found this necessary.

The T forceps are then removed and all external tumors and tabs of skin cut off with a pair of straight scissors, care being taken not to make an incision in the

muco-cutaneous junction, when it can be avoided, as this is the most sensitive point around the anus. This same precaution should also be observed when removing the internal tumors. The field is then dusted with some antiseptic powder and a rubber-covered tampon introduced through a bivalve speculum.

The tampon is allowed to protrude about 1.5 inches beyond the anal orifice. Gauze is carefully wrapped around the protruding portion and packed close to the anus. The anchoring string of the tampon is wrapped around a piece of gauze held close to one side of the tube, and woven in with the other dressings, so as to prevent the tampon's slipping into or out of the rectum. Over this is placed gauze, cotton and a T bandage which is made quite taut. The patient is then placed in bed.

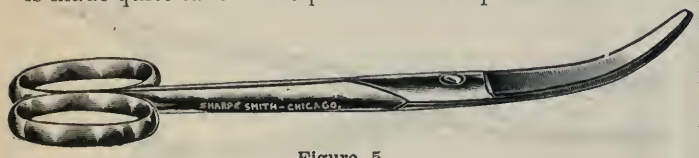

Figure 5.

By operating in this manner there are no tender and obstructive stumps to slough, nor nerves caught and squeezed, producing most excruciating pain, as there are when the ligature method is used; neither are the nerves and tissues painfully burned, as when the clamp and cautery are employed. In lieu of this, a fibrinous exudate is deposited over the operated field, which exudate is neither destroyed nor disturbed upon removal of the dressings. Moreover, the danger of stricture is obviated, as the normal caliber of the bowel is left practically covered with mucous membrane. Neither is the anal orifice contracted, as it necessarily is after either of the above operations.

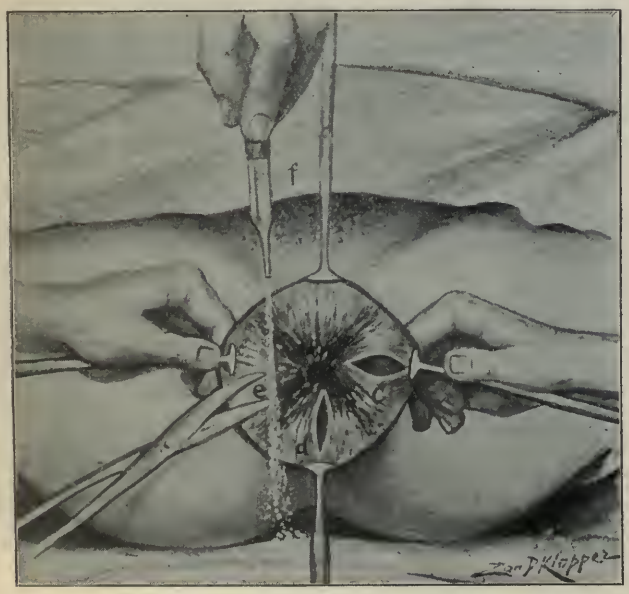

Fig. 6.—Diagrammatic; illustrating method of operating. (*c*) Shows the removal of an ellipse from the apex of the hemorrhoid; (*f*) hot saline solution flowing over the field of operation.

At the end of forty-eight hours the patient is given a cathartic and the tampon removed. Removing it is easy and painless. The movement of the bowels is also painless, and there is, as a rule, little or no bleeding.

From this time on until convalescence is well established, the parts should be washed or irrigated twice a day with an antiseptic solution, and dusted with some antiseptic powder. After the bowels have moved, the patient is instructed to keep them soft for two or three weeks. For this purpose Apenta water is very palatable and effective. Should the patient complain of pain or an aching sensation, a hot sitz bath of twenty minutes' duration is given. As a detergent, small pieces of wet cotton or cottonoid are used. Paper and other hard and rough substances are interdicted.

I prefer the rubber dressing to the gauze and other porous materials because: 1. It is neater. 2. Its removal is painless. 3. As the tender granulation sprouts can not penetrate it, as they do the gauze and other porous dressings, they are not broken off during its removal, neither is the fibrinous exudate disturbed. Hence, the healing process is greatly enhanced. 4. Another advantage, and one of no little moment, is that there is but little or no pain during the first and subsequent movement of the bowels.

This method of procedure, which I have now employed in 138 cases, in 29 of which local anesthesia was used, has been by far more satisfactory than any method previously used. It is very quickly and easily performed. Patients suffer little or no pain, and they are out of bed in a week and often in less time.

As evidence of the advantages of this method of operating over that of any other of which I have knowledge, I will briefly append a few cases.

CASE 1.—Dr. P. had large internal and interno-external hemorrhoids. I operated on him Wednesday, February 19, at the Chicago Hospital. The following Wednesday he came into my office and was examined by Dr. J. M. Mathews, of Louisville, Ky., who spoke very flatteringly of the result. On this day, which was just one week after the operation, besides attending to his regular practice he walked five miles.

CASE 2.—Dr. G., of Montana. I operated on him for large internal hemorrhoids at the Chicago Policlinic Hospital, on Wednesday, March 11. On the following Monday he resumed his work at the Policlinic and on Wednesday, just one week after the operation, he assisted me in operating on Dr. R.'s wife for the same trouble.

CASE 3.—Mrs. R. She is the patient referred to in Case 2. I operated on her March 18, and she was up on the fifth day attending to her household duties.

CASE 4.—Col. H., of Pittsburg. Very large external and internal hemorrhoids. I operated on him at the Passavant Memorial Hospital on March 4. Two of the internal tumors were so large that I made two elliptical incisions in each. He left the hospital at the end of one week.

CASE 5.—Mrs. H. had been operated on for hemorrhoids three years ago by one of our leading surgeons with the ligature method. They returned. I operated on her on Monday, March 4. Her husband, who is a physician, removed the dressings at the end of 48 hours. I saw her on the following Friday, the fourth day after the operation, and she was up.

CASE 6.—Mrs. P., of Caldwell, Kansas, weighed 235 pounds. She had very large internal and small external hemorrhoids. I operated on her at the Passavant Memorial Hospital, March 25, Dr. D. H. Galloway administering the anesthetic. Only eight minutes were consumed in putting her to sleep and completing the operation. She left the hospital and returned home at the end of one week.

CASE 7.—Mr. L., of Canada. I operated on him at the Chicago Policlinic Hospital for internal hemorrhoids, March 27. He was up and left the hospital before the end of the week.

CASE 8.—Dr. C., of Galesburg, Ill., was operated on Friday, May 3, at the Chicago Policlinic Hospital. He was up on the following Tuesday, the fourth day after the operation, attending the clinics and went home before the end of the first week.

Were it necessary I could cite case after case fully demonstrating the advantages of this method of operating. The photo-micrographs were made by Dr. Carl Theodor Gramm, Chicago.

Columbus Memorial Building.

ANATOMICAL TREATMENT OF FRACTURES OF THE FEMORAL NECK.*

C. E. RUTH, M.D.
KEOKUK, IOWA.

In the Association JOURNAL of August 28, 1899, I published a report of 17 cases of intracapsular fracture of the neck of the femur treated according to the method advocated and practiced first by Prof. T. J. Maxwell thirty years ago. It is what I have seen fit to denominate the anatomical method, and is the only method, to my knowledge, that entirely neutralizes the displacing tendencies of muscular action and weight.

Of the 17 cases reported 5 recovered with no discoverable shortening whatever on careful and repeated measurements, 7 gave one-half to three-fourths inch shortening, 3 with one inch shortening, and 2 cases with useless flail-like limbs in which the treatment was abandoned after a few days of trial for lack of co-operation on the part of patient and friends. One death occurred from complications after union had been secured.

Fig. 1.—Muscle pushing itself or other soft parts between the fragments.

Fourteen cases, ranging in age from 25 to 86 years, have obtained union with useful limbs, in no case exceeding one inch of shortening. Union was therefore secured without perceptible shortening in 35 per cent. of cases in which the treatment was continued with anything like regularity.

Slight eversion of the foot was noticed in one case, owing to the lateral pull being too slight and directed too nearly straight outward, instead of the heavy incline upward sufficient to control the tendency to eversion. In two cases of negative results in which treatment was abandoned after a few days, we have the usual outcome of non-treatment, while the amount of shortening obtained in the other cases is much less than the average of those treated by simple extension or other device.

Case 17 was 60 years of age, and so feeble that but little hope was entertained of saving her life; yet she recovered without shortening, and now walks without crutch or cane, without limp or halt. I am convinced that in my earlier cases I could have secured union with less shortening had I known better how much weight was required to overcome muscular action and weight displacement.

The notoriously bad results following fractures of the femoral neck makes apology for this paper unnecessary.

The following cases I wish to report and offer as additional evidence:

CASE 18.—Dr. D., aged 28, was thrown 15 feet from a cart in August, 1894, and sustained a fracture of the right femoral neck. Shortening existed of two inches with eversion and external rotation, treated with extension, counter and lateral extension four weeks. Result, union with one-half inch shortening. Walks without limp in any manner perceptible. Physician, C. A. Runyon, Elvaston, Ill.

CASE 19.—Mrs. Nancy M., aged 68 years, in 1892 sustained a fracture of the left femoral neck. No union was obtained. Two inches of shortening exists with a useless limb, treated by the old sand-bag method, and eight pounds of extension. In November, 1899, she fell and fractured the right femoral neck. Two and a half inch shortening was found on examination. She was treated by extension, counter and lateral extension, and recovered in six weeks with seven-eighths inch of shortening. Can bear weight on the limb and walk with crutches as well as before fracture of the right femur. The left leg still dangles, as it has for the past nine years. This patient would have been confined to the bed or chair the rest of her life had she been treated for the second fracture as she was for the first. Physician, C. A. Runyon, Elvaston, Ill.

Fig. 2.—Course and relations of psoas and iliacus to hip-joint, with thigh flexed at right angles to the trunk.

CASE 20.—Mrs. F., aged 88, sustained intracapsular fracture of the left femoral neck in 1894, and was treated by Dr. H. A. Kinnaman and reported by me in my former paper as Case No. 11. She recovered with a useful limb with one-half inch shortening. She fell Jan. 11, 1900, and sustained a fracture of the right femoral neck. Treatment was not begun for ten days, but was by extension, counter and lateral extension. The treatment was intermittent, owing to the patient being

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

intolerant of restraint. The result was union in four weeks with about one inch shortening. She died two months later of intercurrent malady, nature not determined. Physicians, Drs. Gray and C. E. Ruth.

Case 21.—Tim H., aged 80 years, habits intemperate. Fractured the left femoral neck by a fall on the sidewalk, Nov. 27, 1899. Treated as above. Union was obtained in five weeks; position and motion perfect; shortening one-half inch. Examined and measured leg, April 25, 1900. January, 1901, still well with good use of leg. Physicians, R. H. Fegers and C. E. Ruth.

Case 22.—Mrs. Obediah H., aged 70. Sustained a fracture of the right femoral neck from a fall in January, 1901. Eight days later I was called, and treatment was begun as in the above-mentioned cases. Union was obtained in four weeks without discoverable shortening.

Case 23.—Boy 10 years old fell twenty feet and sustained a fracture of the femoral neck. Treatment as in the former cases, with scarcely demonstrable shortening. Union was secured in four weeks. Physician, A. Ives.

The above physician has had two other cases, 73 and 86 years of age, in which union was secured, but death resulted from exhaustion or complications, and as I have not the histories, can furnish no farther report of them.

Case 24.—David B., aged 60 years, April 10, 1900, was thrown from an ore wagon in a runaway, and thrown down the mountain thirty or forty feet. Examination under chloroform revealed fracture of the femoral neck. Treatment as in the former cases for six weeks. Union was obtained with one-half inch of shortening. He has for several months been driving the ore wagon, and walks with very little limp. Occasionally complains of some pain in the hip in bad weather. Physician, C. M. Tinsman, Adin, Cal.

Case 25.—Mrs. Elizabeth F., aged 86, sustained fracture of the right femoral neck in January, 1900, with shortening, eversion and backward displacement of the trochanter major. Treated by Buck's counter and lateral extension. Union was obtained with no perceptible shortening. The fractured leg gives as good service as before the injury. Physician, Dr. F. A. S. Rebo, Alexandria, Mo., assisted by Dr. W. A. Rebo, of Canton, Mo.

The first indication in the treatment of all fractures is correct adjustment; second, immobilization; third, overcoming muscular action which would tend to disturb the normal relations. We should be careful to eliminate all our own errors before blaming Nature with our unsatisfactory results. In these cases there is no muscular effort or influence acting on the upper fragment. The position of the lower fragment will depend upon the position of the patient, the kind of retaining force, and his own muscularity; for muscular action is of more importance in determining results of fracture here than anywhere else in the body. This is due to the great number of powerful muscles passing over the fracture line to be inserted somewhere beyond, and which must exert a powerful displacing force.

The position, at least for a time, that must be taken by these cases is upon the back, and the displacement is known to be upward, backward and outward rotation, with all the internal displacement of the lower fragment which the muscular tissues will permit.

The pronounced tendency to eversion and external rotation is increased greatly by the external rotary power of the psoas and iliacus, which was neutral or else an internal rotator now must be a pronounced external rotator, because the insertion into the back and internal portion of the upper end of the femoral shaft and lesser trochanter throws the line of action internal to the point of resistance, whereas it was formerly external. The result is that we have the following muscles acting to produce the following results:

Those pulling nearly directly upward and tending to shorten the limb by over-riding the fragments, are the sartorius, rectus, gracilis, semi-tendinosus, semi-membranosus, long head of the biceps, vertical portion of the abductor magnus.

Those pulling very strongly inward as well as upward are the adductor magnus, except vertical portion; adductor longus, adductor brevis, pectineous, gluteus maximus, gluteus medius and gluteus minimus.

Those which pull almost directly inward and rotate outward are the pyriformis, obturator intermus, gemellus, superior and inferior, obturator externus, quadratus femoris, lower half of gluteus maximus.

Those which pull inward, upward and rotate inward, are the tensor vaginæ femoris and the anterior portions of the gluteus medius and minimus.

Fig. 3.—Fracture of neck of femur in Case 2. At 72 years of age, used 20 years afterwards. No perceptible shortening. Physician, Prof. T. J. Maxwell, Keokuk, Iowa.

Those formerly internal rotators exerting a strong upward pull and now external rotators, often drawn directly between the fragments, and absolutely preventing approximation of the bony parts, psoas and iliacus (Fig. 1).

It will thus be seen that the external rotary force greatly predominates over the internal because of the conversion of internal rotary force of the psoas and the iliacus to external, besides the power of the limb's weight to accomplish the same ends. Lastly, we have the important displacing force weight tending to carry the upper end of the lower fragment behind the line it should occupy because its old attachment support is gone. Posterior displacement and external rotation are only limited by the Y ligament.

Adjustment of the fragments is best accomplished by flexing the thigh upon the abdomen to relax the psoas

and the iliacus, bringing them above the fracture line, thereby preventing them from being permanently caught between the fragments (Fig. 2).

This position also relaxes nearly all the external rotators or changes them into abductors; then make vertical traction on the shaft of the femur, which now stands at right angles to the trunk, while moderate evasion is being maintained; next abduct to the normal line and make extension in the long axis of the trunk, while an assistant makes traction one-half to two-thirds as strong outward, slightly upward and forward from the upper end of the femoral shaft. These manipulations should be made by firm, steady traction, not by jerks, which is to become continuous by Buck's extension with a weight of from ten to twenty pounds, according to the muscularity of the patient, with elevation of the foot of the bed enough to counteract the tendency of the patient to slide down to the foot. This means an elevation of from six to fifteen inches. A binder's board, or other splint material, should now be molded to the upper inner aspect of the thigh, over which a band of adhesive plaster four to six inches wide should pass outward, upward and sufficiently forward that the weight over the pulley

Figs. 4 and 5.—Vertical section of femoral neck fractured 20 years before. Case 2 of former report.

shall overcome the internal pull of all the rotators and adductors, and at the same time raise the lower fragment to its normal level and maintain it there. It must entirely overcome the tendency to external rotation.

The weight on this lateral pulley will be from five to fifteen pounds, according to requirements. The side of the bed corresponding to the injured side of the patient must be raised enough to prevent the individual from being drawn out of position toward the lateral pulley. Patients so treated will have absolutely no pain whatever after spasmodic muscular action is entirely overcome.

The claim has been persistently made that bony union can not be expected. In Case No. 2, treated by Dr. T. J. Maxwell in 1881, bony union was secured, as proven by postmortem specimen which I now present you (Figs. 3, 4, 5). This patient was 72 years of age when he sustained the fracture. He made a good recovery without perceptible shortening, and had good use of his leg for twenty years.

The specimen shows the line of union very distinctly. There was slight eversion, but not sufficient to cause the patient any marked annoyance. This case is sufficient to forever settle the question of Nature's ability to repair these injuries if given a chance.

The figures I herewith present will show the actions of the psoas and iliacus muscles in fractures of the femoral neck; and as some might question the correctness of the photographs, I will illustrate by models to which I have attached artificial muscles (Figs. 1, 2 and 6).

The only essential illustration difference between the action in life and on the model, however, is the anterior portion of the capsular ligament will probably be intact to its lower border and prevent the muscular tissue from falling between the fragments; but muscular action tends to force the capsule in such cases between

Fig. 6.—Shows normal position, relation and line of action of years before. Case 2 of former report.

the fragments, and thus interfere with union quite as much as though the muscular tissue itself occupied the space.

We do not come to you with a single case in the hands of a man of slight experience, but with 25 cases of unquestioned fracture of the femoral neck in the hands mostly of men of large experience. In 22 of these cases union was obtained; useful limbs were secured in persons ranging in age from 10 years to almost the extreme limits of old age, and yet the shortening was no more than one inch in any; and after the most careful measurements no shortening whatever was discoverable in six of the cases.

In one of the cases reported with one-half inch shortening, the physician in charge informed me that he could find no shortening, and that the patient walked without a particle of halt; but one-half inch shortening was claimed in the prosecution of a suit brought against his employers for damages. This man fell thirty feet when the fracture was produced. In some of my own cases I am certain that I did not use heavy enough weights, and in others the treatment was interrupted occasionally by having the weight removed to satisfy some meddlesome attendant, nurse or the patient.

The only failures to secure union were in two cases that absolutely refused to have the treatment carried out. I might cite you many cases of flail-like limbs from this cause, as can be done by most physicians of any considerable practice. Where little or no shortening took place, and the limb was functionally perfect, there can be no doubt that the union was bony.

Whatever may be the opinions in regard to repair of this bone, results that are almost perfect, and make the patient comfortable while repair is taking place, are certainly worthy of our attention, endorsement and most earnest efforts to establish, even though most of the patients are advanced in years. The usefulness of this plan of treatment is not alone limited to fractures of the femoral neck, but is equally applicable to the treatment of hip-joint disease with or without operation in cases confined indoors.

In some of these cases treatment was not begun until several days after the injury, and in some the treatment was interrupted occasionally for a short time. In no case was pain complained of after the first day, if weights were enough to prevent muscular spasmodic disturbance of the fragments.

Fig. 7.—Showing Buck's extension and lateral extension. Foot of the bed raised; the side of the bed corresponding to the injured limb is also raised to overcome tendency to displacement towards the lateral pulley.

By this plan of treatment the patient can be raised, if needs be, to the sitting or semi-sitting posture for the purpose of cleansing. Some of these cases had bedsores, and were lying in their own excrement and suffering severely when the treatment was begun. These were raised daily to the sitting posture, cleansed and the sores healed during the use of the extension treatment.

The patient can be easily handled in the use of the bedpan. The method is easy of application, and only fulfills the indications we require for all other solutions in continuity of bone, viz., securing coaptation of fragments without the possible intervention of the soft parts, overcomes all displacing tendencies of powerful muscular action instead of ignoring the action of more than one-half the muscles and displacing power of the limb's weight (Fig. 7).

The results prove that it is not necessary to allow most of the fractures of the femoral neck in the aged to produce cripples for the rest of their lives, or that they should suffer, except from the confinement, and that could be scarcely less by the plan of treatment proposed than to give the patient every possible liberty during the time required for procuring union. It also proves that the influence of the synovia is nil as a preventive of union. I do not wish to be considered as claiming that perfect results can be confidently expected in all, or in fact any of these and thereby invite prosecution for malpractice in every case of failure. What I do want, however, is to see the day when we will be able to lay aside prejudice and custom, if need be, and use the method that will give the best results. By this plan of treatment considerable freedom of movement can be allowed the upper part of the body as well as the opposite limb; so that the confinement is usually not irksome after the first few days.

DISCUSSION.

DR. C. E. THOMSON, Scranton, Pa.—My patient, an old man, 62 years of age, sustained a fracture in August, 1899. He was a miner by occupation, and the injury was caused by a fall of rock. No diagnosis was made at the time of accident. He was bedridden for three months; at that time he came under my care. A diagnosis of fracture of neck of femur was made and afterwards confirmed by *x*-ray photographs. The operation recommended by Gillette, of St. Paul, was proposed, accepted, and performed on Dec. 12, 1899. It consisted of a horseshoe incision around the trochanter major down to the periosteum. The flap being elevated, a second incision including periosteum and a section of bone (about one-third thickness of shaft) 2½ inches below trochanter was made, liberated with an osteotome, and turned up. This enabled us to get nearer the seat of injury. In this particular case the fracture was found to be comminuted. Several pieces of bone were removed. The fractured ends were then adjusted and a solid silver nail three-sixteenths of an inch in diameter and two and one-half inches long was driven through the neck and into the head of the femur, as the skiagraph shows. We were gratified to find that the nail held the fragments quite firmly together. The wound was closed with catgut suture and the entire leg and body encased in a plaster-of-paris spica, extending from the axilla to tip of toes. Patient had no elevation of temperature. The initial dressing was removed at the end of two weeks. At the end of five weeks the plaster-of-paris spica was removed and patient allowed to move about. He left the hospital on crutches and improvement continued. Seven months after operation he complained of pain, and a few weeks later a sinus appeared at seat of incision, and this was followed later by an accumulation of pus in the gluteal region, which was evacuated under cocain, but a slight sinus persisted. Improvement continued until last month (eighteen months after operation) which was the last time he was seen alive by us, when

he walked into the hospital without cane or crutch. He had 90 degrees of free and painless motion. Last Saturday night he retired as usual, and was found dead in his bed at 5 a. m. The coroner made a diagnosis of "heart trouble." I secured this specimen which is now being passed around. You will see, both by the specimen and the *x*-ray photographs, which

were taken directly on the plate, that the bony union is firm and complete.

Dr. D. N. Eisendrath, Chicago—I think we should discriminate between the different cases of fracture of the neck. The percentage of mortality is still very large and the reason for this is we do not recognize the importance of the fact of getting elderly patients up as soon after the fracture as possible. They die of bed-sores and hypostatic pneumonia; they are people with frail constitutions who can not stand confinement to bed, just as the last speaker showed us. The ideal treatment for these cases is in the use of the Thomas Ridlon hip-splint. It enables those people above the age of 60 and 65 to get up within twenty-four hours after the fracture. We confine these patients for 4 or 6 weeks in bed and then obtain no better results than obtained in ambulatory treatment.

Dr. T. J. Maxwell, Keokuk, Iowa—I had my first case of intracapsular fracture of femur in 1870. The case was a spare woman aged 52. I found the foot everted and leg shortened. I put her in a Day splint and made extension; she suffered pain continuously. At the end of a week there was flattening of the hip and I devised this plan or method that has been presented to you by Dr. Ruth. I put her under lateral extension and she recovered without shortening. Ten years afterwards I had another case—the bone that has been presented to you of an intracapsular fracture. However, this bone may not have been an intracapsular fracture. It might have been an impacted fracture, except for this: There were two inches of shortening, eversion of the foot and crepitation on extension and rotation. Now, the 25 cases presented to you ought to be evidence sufficient of the benefit; where there is no wearing, no pain after extension, the bed-pan can be used. This bone belonged to a man I treated 20 years ago. He was nearly 72 years old at the time of fracture. He had walked on it for twelve years.

Dr. W. W. Grant, Denver—This specimen is a most important one, if the man did have an intracapusular, impacted or non-impacted fracture. In examining it I am forced to express a grave doubt of its having existed. The cancellous tissue of the neck and the compact substance of the under or lower surface do not reveal any evidence of disease or past lesion whatever. The upper surface of the neck, near the trochanter shows a few osteophytes—evidence of old inflammation.

I call attention to the fact that the neck of this bone. from a man 90 years old, is of normal length. If there was an impacted fracture, how could you explain it? If, as stated, there was immediate shortening of two inches or more, with loud crepitus, it would be equally difficult, if not impossible of satisfactory explanation. Fracture of the rim of the acetabulum,

Army Medical Museum.
Rarifying osteitis with interstitial absorption.

with dislocation, would, with the extension treatment used, better explain the condition past and present.

There is a specimen in the Army Medical Museum at Washington which involved the very question at issue. I have examined it repeatedly and carefully. It looks something like this specimen, showing more evidence of the influence of pressure in walking. The neck is shorter and the angle more acute. The man, an old soldier, was treated for a fracture of the neck many years before his death. Dr. B. E. Frayer, a retired army surgeon, now of Kansas City, made the postmortem and sent the specimen to the surgeon-general as an

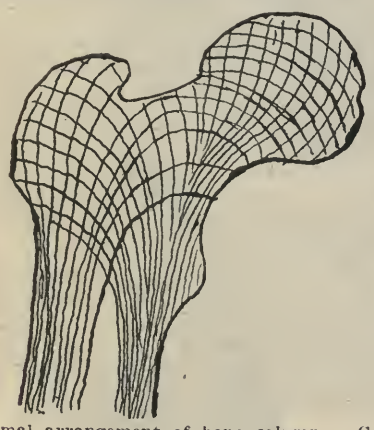
Army Medical Museum.
Rarifying osteitis. Front view.

illustration of bony union. A Philadelphia surgeon, visiting Washington, examined it. The specimen was sawed lengthwise and disclosed satisfactory evidence that no fracture had existed. It was regarded as evidence of interstitial absorption from traumatism, notwithstanding the doubt entertained by some of such a condition.

Yet, there seems no doubt of a dry form of inflammation, with fatty degeneration, and change of angle of neck, the latter produced or promoted by walking and absorption. Such a condition, with or without injury, seems more rational than the conclusion that the specimen here presented—perfect in coaptation of fragments, bony union and outline—was a complete fracture of the neck.

The condition involves deeply not alone the question of treatment and the interest of the patient, but in a medicolegal sense, the welfare and reputation of the surgeon.

CHAIRMAN—How old and how many years between the fracture, in the Washington specimen, and death of the patient?



DR. GRANT—He was about 44 at time of injury and he died 10 to 20 years afterwards, I believe.

DR. MAXWELL—How can he account for two inches of shortening with crepitation on extension and rotation.

DR. GRANT—You might have it in the acetabulum without fracture of the neck of the bone and that extension would reduce it and you would have no shortening. I have often seen that crepitation mistaken for fracture of the neck of the bone.

DR. A. C. BERNAYS, St. Louis—When I saw that specimen at the Tri-State meeting four months ago I was skeptical; I thought it was not the bone of a man 90 years old, or a woman. I was inclined to doubt it as has been done by others this morning. Dr. Maxwell showed me the specimen at Keokuk. The thing impressed me so much that I got the superintendent of the poorhouse to let me have the bones of two of the oldest men that died during the month. They were over 80 years of age; I would not state now the exact age. I saw bones there just as solid in texture and as firm as that bone is. I became convinced that the bone is the bone of a man over 90 years of age. I simply want to bring that point out, because it is no more than just to the gentleman who presented it and to Dr. Maxwell.

DR. C. E. RUTH, Keokuk—I thought that this specimen might be questioned, and referred to that fact in my paper

Normal arrangement of bone columns. Gray.

because the result is so nearly perfect. If this fracture had occurred in the hands of a man of slight experience and ability, I might question the diagnosis of a fracture of the neck of the femur with a shortening of two inches and complete eversion of the foot; but Dr. T. J. Maxwell, a man of unquestioned ability and enormous experience, had this case, and now in regard to this specimen twenty years' time has elapsed. The man was vigorous and muscular; that shows by the prominence of the lines, tuberosities and tubercles. Again, I said the line of solution of continuity shows. It does show, but not as pronouncedly as in a case of marked displacement of the fragments; consequently, there is no large callus to mark the line of solution of continuity. I said there was eversion of the foot following the injury until the patient's death. Can you question that fact when I can barely pass this lead pencil between the great trochanter and the head of the femur? Did you ever see a femoral head in a well-developed individual as close to the great trochanter as that in a bone not previously broken? I never did, and I have examined a considerable number. This man walked with eversion of the foot from the time of his recovery from the fracture until his death, when it was removed postmortem. The only point where you can see evidence of solution of continuity externally is on this roughened line on the anterior surface of the neck nearer to the head than to the intertrochanteric line. Did any of you ever see so prominent a roughened line on the front side of the femoral neck between the intertrochanteric line and margin of the cartilage in a femoral neck not previously broken? Not by any means. Why? Because there is no capsule or other tissue requiring a roughened surface for attachment to the anterior part of the femoral neck. Why do we have evidence of solution of continuity on the anterior surface indicated in this roughened line if it does not show on the posterior surface? The reason is, we had an eversion of the foot and there was not so close an approximation of the fragments on the anterior surface as there was on the backside, and then the fracture line ran so close to the base of the neck at the great trochanter that external union is not discoverable. Many of you have seen a union of bone not discoverable by examination of the surface when adjustment was perfect. We have made a longitudinal section to show the condition of the bone inside. You can see the position from this point to behind the center of the bone, the dense compact tissue extending along the line of fracture in a curved direction [illustrating diagrammatically]. Let this represent the head, the great trochanter and the lesser trochanter. Now, here we have the solution of continuity running across about this line [indicating] as we have indicated by the roughened line on the front side. When we section the bone we find that the line does not run through all the thickness in the same position or course. We find here dense, compact tissue extending from the inner side just above the lesser trochanter beyond the center of the neck, where we have the more pronounced projection of compact tissue (callus). This is not the only specimen we may obtain. We

Heavy shading indicates position of compact tissue from callus, broken lines between indicate cancellous tissue devoid of columns; other lines practically normal, save neck has been drawn much too long.

have had twenty-five cases in which the diagnosis was beyond question. There is one case reported by a physician where the fractured leg has a better function than the other, and this patient was 86 years old at the time of the accident and there is no perceptible shortening.

In regard to pinning of the bones, as was mentioned by Dr. Thomson, this beautiful specimen shows bony union. A skiagraph has been taken and it shows three-fourths inch of shortening. This plan was all right if it was necessary. I do not say it is not necessary in every case; it has not been in my experience. It is certainly a good method if we have no better. I do not say we should never use it, but when we can avoid an operation in these cases we should do it, and not add an additional burden to an already serious condition. Unquestionably, fracture of the femoral neck in an aged person is serious. If we can avoid operation complications it is an important matter, and should always be done except in cases of delayed or non-union; then the pinning is certainly good surgery. I have not much experience with the Thomas splint. It would be all right if it held the femur out and forward as well as down. It makes no provision whatever for the tendency of the upper end of the lower fragment to drop behind the normal line when the individual lies on the back, as he will part of the time. It makes no attempt whatever to bring the femur out in its normal position. The trouble has been, in the treatment of these fractures, that we make our extension directly downward, instead of in the line of the neck of

the femur. You would not think of applying this principle of opposing muscular action to any other part of the body as here. We seem to forget that some of the muscles pull inward, while others pull directly upward; so it is absolutely necessary that we apply two forces, and that we overcome the muscular action so that the resultant of the two applied forces shall be in the direction of the neck of the femur and give the result of one acting in the long axis of the body, and the other in an outward direction.

HERPES ZOSTER OPHTHALMICUS WITH BRIEF REPORT OF FIVE CASES.*

WM. C. BANE, M.D.

Clinical Professor of Ophthalmology and Otology, Denver College of Medicine; Ophthalmologist and Otologist to St. Joseph's Hospital; House of the Good Shepherd; National Jewish Hospital for Consumptives; C., R. I. & P. Ry.; Consultant for Diseases of the Nose and Throat to the State Home for Dependent Children.

DENVER, COLO.

Herpes zoster ophthalmicus has been well known for the past third of a century. It is an acute inflammatory affection appearing in the course of the first and second branches of the fifth nerve, and is almost invariably unilateral. It occurs in elevated groups of firm oval or circular vesicles, on an edematous base, at the terminal points of the nerve filaments. The groups of vesicles do not all appear at once and their area is limited to the median line, and to filaments of the branches involved in the inflammation.

Herpes zoster ophthalmicus is a neuritis in which the ganglion of Gasser is involved, as has been proven by De Wecker. Charcot and others have demonstrated that in herpes zoster the ganglion of the posterior root of the spinal nerve is inflamed.

The disease is characterized by severe pain, which usually precedes the eruption by a period varying from hours to several days. The pain is generally sharp and shooting, and interferes with sleep and labor, but sometimes the pain is dull and causes less disturbance.

In the ophthalmic type, the first branch is the one most frequently involved, which includes the upper lid, forehead as far as the scalp, and also the nose. The second branch includes the lower lid, superior maxillary region, upper lip, and over the malar bone.

When the nasal branches are involved, the cornea is very likely to suffer, though exceptions to this rule have been observed.

The error of diagnosing herpes zoster ophthalmicus as facial erysipelas has frequently been made. Some of the typical features of the two diseases are as follows:

HERPES ZOSTER OPHTHALMICUS.	ACUTE FACIAL ERYSIPELAS.
1. It develops as a bright red inflammation limited to one side of the face, and appears in clusters of firm vesicles on an edematous base, that does not spread when once developed.	1. It develops as a purplish-red inflammation that spreads over all parts, without regard to the median line; the vesicles, when they appear, are in large blebs.
2. The eruption is preceded for hours or days by severe neuralgic pains, and as a rule no fever or rigors mark the disease.	2. It is ushered in by a chill, and marked elevation of temperature, also a burning sensation in the inflamed tissues. A dull headache may be present.
3. The inflammation being of a neurotic origin, it is limited to tissues where the nerve filaments terminate.	3. The inflammation being due to infection by the streptococcus erysipelatis, spreads through the lymph channels, and when deep invades the lymphatic glands.
4. The inflamed points are exceedingly painful to the touch.	4. The inflamed tissue is moderately tender to the touch.
5. Groups of punched-out scars are invariably left in the wake of the vesicles and remain through life.	5. Seldom is there a trace left after the exfoliation of the skin, though sometimes a thickening of the cellular tissue remains.

The following cases of herpes zoster ophthalmicus have come under my observation:

CASE 1.—On Jan. 8, 1891, I saw Mrs. H. C. K., in consultation with Dr. C. Jane Vincent of Alleghany City. Some seventeen days previous to my visit, the patient had developed herpes zoster ophthalmicus of the left frontal and temporal regions. The patient had suffered severe pain in the head and the left eye. The vision was reduced to counting fingers at two feet. She had considerable congestion of the eyeball, and a small central ulcer of the cornea. The iris was free and responded to light and accommodation. One week after my first visit the ocular congestion had subsided, the corneal ulcer had healed and vision so improved that she could see the features of a face a few feet from the eye. No record was made of any vesicles on the nose.

CASE 2.—Rev. J. S. T. M., aged 65, consulted me May 5, 1891. He stated that one month previously his left eye had been injured by a bit of steel. His family physician removed the foreign body three days after the accident. He then developed what was diagnosed facial erysipelas, the disease being confined to the left side of the forehead and nose with involvement of the left eye. He gave a history of having had three corneal ulcers and iritis of the left eye. Upon examination I found a moderately congested eyeball and a slight opacity of the cornea marking the location of the ulcers. There were also several pigment deposits on the anterior capsule of the lens, marking the points where the iris had been adherent. On the forehead, the supra-orbital ridge and the nose were the scars where vesicles had existed. Vision of the right eye was 6/12, and that of the left eye 6/18. The patient remained under my care for about a month, during which time his vision improved and the congestion of the eyeball in great part disappeared.

CASE 3.—In February, 1896, I was called by Dr. J. W. Higgins to see Mrs. J. W. P. The patient was a delicate woman of 56 years of age. She was suffering with intense neuralgic pains in the left side of the head and face. Her face presented the typical appearance of an aggravated form of herpes zoster ophthalmicus, involving the first and second branches of the trigeminus. The area involved was of a bright-red color with large groups of vesicles on the forehead, nose and cheek. The left eye was moderately congested and painful, but no involvement of the cornea existed. The neuralgic pains were excruciating. Two weeks after I saw the patient she became insane and was taken to an asylum, where she remained for four years, finally dying without regaining her mental balance. Upon inquiry of her husband I learned that she had manifested some evidence of mental disturbance for a month previous to the development of the herpes zoster.

CASE 4.—E. A. P., aged 36, a nurse, was referred to me Nov. 30, 1899, by Dr. H. T. Pershing, on account of having some irritation of the left eye. Patient came to Colorado eight weeks previously, owing to some pulmonary disease. Two weeks after reaching Denver he was taken with chills, having three or four daily for a week, with a temperature of 100 to 104. On Oct. 24,

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

1899, the left side of his face became of a bright-red color and somewhat swollen. The inflammation extended from the scalp down the median line, including the left half of the upper lip and across the cheek and temple. Patient applied to a hospital and was refused admittance, on the ground that his facial disease was believed to be contagious, but was referred to another hospital where he was admitted as a case of facial erysipelas and there he remained four weeks. Three days after, the face became inflamed, clusters of clear firm vesicles formed on the inflamed area, those on the left side of the nose being as large as the little-finger nail. Crusts appeared later and those on his nose became quite dark in color and the patient states that the crusts were removed about the ninth day after the vesicles appeared, leaving painful ulcers. For the next twenty-four hours he experienced an intense itching and burning sensation over the affected area, and the following day a new crop

Herpes zoster ophthalmicus.

of vesicles appeared and the left eye became very painful, the lids swollen, and of a purplish hue. Some twelve hours later most of the swelling subsided and the color changed to a bright red. The eye remained painful and he was unable to bear the light. Upon examination (five weeks after the first appearance of the disease) vision of the right eye 6/6, left eye 6/30. Marked photophobia existed in the left eye. The lids were somewhat swollen, of a reddish hue and tender to the touch. Partial anesthesia of the upper lid existed. Conjunctiva was slightly congested, the cornea clear and partially anesthetic. Pupil was moderately dilated from atropin. There was hyperemia of the retina, otherwise no fundus changes perceptible. The left side of the nose showed loss of tissue and considerable cicatricial contraction, not unlike the appearance left by smallpox or a burn. In the scalp near the forehead on the line of the parting of the hair was a cluster of depressions marking the seat of a group of ulcers. The depressions on the temple were not very plainly outlined. One clean-cut depression existed on the cheek about an inch to the left of the lower half of the nose. The skin of the left temple was anesthetic on a line with the brow, and partial anesthesia existed over the rest of the temple and forehead to the median line and back into the scalp.

Some error of refraction was manifest in left eye, the correction of which brought the vision up to 6/12. Patient remained under my care for several weeks, during which time the neuralgic pains diminished, the photophobia became less and a slight improvement in the anesthetic areas occurred.

CASE 5.—Miss A., aged 22, came under my notice in November, 1900, through the courtesy of Dr. J. M. Blaine, under whose care the patient was at that time. She was passing through a moderate attack of herpes zoster ophthalmicus of the left side of her face, involving the first two branches of the fifth nerve. Three group of vesicles were present, one on the forehead, one on the temple and one on the lower eyelid. The eye was free from irritation. The patient had a great deal of neuralgic pain for several days previous to the developing of the eruption. After the disease had been properly diagnosed and the patient was improving she met another physician who told her she had facial erysipelas.

Remarks:—The first case was typical in its course and sequelæ. The disease was correctly diagnosed and the indications met by the attending physician. The second case, an intelligent gentleman, had been under the care of an eye surgeon of repute, and yet the disease had been diagnosed facial erysipelas. The sequelæ were typical of herpes zoster ophthalmicus, in the scars on the face and maculæ of the cornea, the latter being with the rule, that is, when the nasal branches are implicated. The third case presented an interesting feature in that the patient manifested some mental disturbance a month previous to the development of the herpes, and two weeks afterwards became so unbalanced mentally as to require close confinement, in which she was kept until she died. However, I am led to believe that the herpes zoster was merely a coincident in the mental disease and not a part of the central nervous affection. The fourth case, a nurse, spent a month in a hospital under the care of a very successful practitioner, and yet the true nature of the disease was overlooked. The affection was an exception to the rule, in that the cornea escaped ulceration, while the inflammation of the nose was very severe, bordering onto the gangrenous type. The fifth case had a moderate attack, neither the nose or the eyeball being involved.

Two of the five cases were males. Four were left-sided. Three of the five were diagnosed cases of facial erysipelas. Two had corneal ulcers. Two had severe nasal involvement without implication of the cornea.

The Medical Balloon-Ascents.—Four balloons were placed at the disposal of certain physicians of Paris who wished to study the effect of high altitudes on the blood, etc., free from the fatigue of mountain climbing. Drs. Tissot, Hallion, Raymond, Jolly and Henri were among those who made the ascent. The tests were made on large dogs or on the physicians themselves. The results harmonized in ever case and showed a marked and rapid increase in the number of red corpuscles in the blood when an altitude of about 9000 feet was reached, but this increase disappeared during the descent. Dr. Gaule had previously reported similar tests on himself, his wife and children, with the same result, the temporary augmentation of the red corpuscles at the high altitudes. The physicians communicated their experiences to the Society of Biology.

CORNEAL LESIONS IN ACQUIRED SYPHILIS.*

WILLIAM H. WILDER, M.D.

Assistant Professor of Ophthalmology in Rush Medical College: Professor of Ophthalmology, Chicago Policlinic; Surgeon to Illinois Charitable Eye and Ear Infirmary.

CHICAGO.

The comparative infrequency of lesions of the cornea as manifestations or results of acquired syphilis, and the opinion of many ophthalmologists, among others Mooren, Panas and Perrin (according to Denarié) that corneal lesions are not caused by acquired syphilis, have prompted me to present this subject for the consideration of the Section on Ophthalmology, and to report some cases that have come under my own observation in which the relation of cause and effect seems to be clear.

The relation of inherited syphilis to interstitial keratitis seems to be well established, and the etiology of the disease can usually be fairly demonstrated in a large majority of the cases. But in a considerable number of cases of deep-seated inflammation of the cornea which simulate in many respects the interstitial keratitis of inherited syphilis, no confirmatory evidence of such taint can be shown; and it is in such cases that careful examination should be made for the history and signs of acquired syphilis.

Let me relate briefly the histories of three cases of deep-seated corneal disease in which syphilis seemed to be clearly the cause; in the second case the lesion was very similar to that seen in an ordinary case of interstitial keratitis; in the others the similarity was not very close.

CASE 1.—James B., colored, aged 29, came to my clinic at the Illinois Charitable Eye and Ear Infirmary, October, 1895, with trouble of right eye. There was considerable circumcorneal injection; some lachrymation and photophobia. He stated that the inflammation of the eye began about four weeks previously with sensitiveness to light and watering, and that soon after a spot was noticed on the upper part of the clear portion of the eye. It was not improved by the treatment that had been given by some physician.

Examination showed a triangular-shaped area of infiltration in the cornea the apex of which approached nearly to the center of the cornea, and involved a good part of the upper inner quadrant and which at first glance resembled a sclerotizing keratitis seeming to be almost continuous with the sclerotic, that is, there was no clear corneal space at the margin. Closer inspection with a Coddington lens, however, showed this opacity was deep seated, was more dense at the periphery and seemed to be made up of numerous clusters or foci of infiltration which were thicker than the intervening spaces. The corneal epithelium did not appear steamy, and there was an absence of vessels in the opaque patch. The iris responded rather sluggishly to light, but the pupil dilated evenly under atropin. The ciliary injection was more intense near the site of the corneal lesion. The left eye was normal. The patient stated that eleven months previously he had a hard chancre on the penis which got well in about two weeks. He also had a swelling in the groins, not particularly painful. Some two weeks later he had blotches on his face, body and arms, and also sore mouth and sore throat, and rheumatic pains at night. For this infection he had been under treatment at some clinic. At the time I saw him there was quite a number of nodules on the face and arms, the largest about the size of a pea; small patches of deeper pigmentation on the face, breast and arms, which he described as the remains of the old rash. The superficial glands of the body were enlarged; the epitrochlears being distinctly perceptible. The treatment embraced atropin, hot applications, protection of the eye from light and potassium iodid 20 grains t. i. d. For the first week or ten days the case did not seem to improve, but the eye became more irritable and the injection more intense. Then a rapid improvement began, the dose of the iodid being increased to 30 grains t. i. d. and the opacity began to clear up. At the end of four weeks the injection had entirely disappeared and the cornea was nearly of its normal transparency. The magnifying glass still showed some faint areas of cloudiness. The patient had good vision. He passed from my observation and I had no opportunity of seeing him later.

CASE 2.—Mrs. J., aged 34, well developed and nourished, and with good family history, was seen by me Jan. 20, 1897. She was married at the age of 24, and had two healthy children, which at the time I first saw her were living, aged 9 and 7 years. Some two years after the birth of her second child, she suffered from rheumatic pains, says her hair fell out a great deal, and that she had a peculiar rash on her face and body, together with sore throat. A little later she aborted at the third month of pregnancy, but still later carried a child nearly to time, but it was born dead. She has not been pregnant since.

About two weeks previous to her first visit to me the left eye became irritable, sensitive to the light and watered somewhat. She thought she had taken cold in it, and used some simple remedies, thinking it would promptly recover. When I first saw her I found the following condition: There was well-marked circumcorneal injection, more intense at the upper part of the cornea. Deep in the substance of the cornea were seen numbers of rather dense grayish spots of opacity between which the corneal structure seemed to be more or less hazy. These spots varied from 1 to 2 mm. in diameter, but were not distinctly outlined, their margins merging imperceptibly into the general haze. The corneal loop showed them to be infiltrations in the deeper layers of the cornea. The epithelium did not seem to be disturbed, and there was none of the steaminess of the cornea that is usually seen in interstitial keratitis. As is usually the case in that disease, the periphery of the cornea was first affected, the central portion being quite clear. The pupil reaction in both eyes was good, and there was no evidence or previous history of iritis. The right eye was normal. R. V. =20/20. L. V. = 20/40; with +0.50 Sph. slight improvement. Ophthalmoscopic examination was negative.

The posterior cervical glands were enlarged and indurated. Treatment was instituted at once, the patient being instructed to use a drop or two of 1 per cent. atropin solution in the affected eye three times daily and to protect the eye from light. She was given also 20 grains of potassium iodid three times daily. The opacity became more dense and invaded the central portion of the cornea so that the vision of the left became reduced to 10/200. Unlike an ordinary case of interstitial keratitis, there was very little vascularization of the cornea, almost none, although a few very minute vessels could be seen pushing in at the periphery. The right eye was not in the least affected. After a few weeks of the

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

treatment the condition began to mend, the opacity growing lighter at the margins of the cornea and clearing away toward the center. At the end of two months after she was first seen, the cornea had become quite clear, with only a few indistinct faint nebulæ, seen only by oblique illumination in the upper part of the cornea. The vision of the eye had improved to 20/30.

Case 3.—A man, aged 26 years, was seen by me in November, 1900, in my clinic at the Illinois Eye and Ear Infirmary. He was complaining of some discomfort in the right eye, the vision of which was lowered to 20/60. There was considerable ciliary injection. Five or six yellowish-gray spots of opacity varying in size from 1 to 1.5 mm. were seen in the cornea not far from the upper and outer limbus. The magnifying glass showed these to be infiltrates into the deeper layers of the cornea. Over the two spots nearest the center of the cornea, the epithelium was raised so as to form a distinct little vesicle, the contents of which seemed to be perfectly clear and colorless, when viewed with a lens from the side, although it rested on the yellowish-gray spot of infiltrate in the deeper cornea. The left cornea was normal. This patient stated that he had been infected with syphilis about fifteen months previously, and gave a distinct history of the disease. About five months after the initial lesion he said that he had a severe and painful inflammation of the right eye that had been pronounced iritis. At the time he was first seen the right pupil was irregular, and the use of atropin showed several old posterior synechiæ and pigment spots on the anterior capsule of the lens.

He was immediately given active antisyphilitic treatment and atropin locally, with the result that the opacities disappeared rapidly, and were entirely gone at the end of three weeks. The little vesicles disappeared without ulceration, and no trace of them or of the underlying infiltrations was left. The vision improved to 20/40.

I was inclined to regard this case as similar to the keratitis punctata described by Mauthner. In all of these cases the lesion affected only one eye, and this may be said to be the rule, whereas the keratitis from inherited syphilis is usually symmetrical.

As to the frequency of acquired syphilis of the cornea there is considerable variance of opinion. Hutchinson, in his work on "Syphilis," says: "Keratitis and complete deafness in the acquired disease are almost equally rare, but when they do occur it is in the secondary period."

Roosa, in an editorial interpolation in Schmidt-Rimpler's "Ophthalmology and Ophthalmoscopy," says: "As to acquired syphilis, I think it is very rarely, if ever, the cause of diffuse keratitis." According to Denarié,[1] Mooren, Panas, Perrin and many other French authors deny that acquired syphilis can influence the cornea. In the same article he reports a case of indubitable keratitis interstitialis caused by acquired syphilis, and also a case of gumma of the cornea, relieved by antisyphilitic treatment. The patient died of cerebral gumma, as shown by the autopsy.

Pulcharia Jakolewa,[2] analyzing 63 cases of diffuse interstitial keratitis, found that 10 per cent. of them were in patients older than 21 years. Two cases were distinctly due to acquired syphilis. Werndly,[3] among 15,000 patients, observed 42 cases of keratitis interstitialis, only nine cases of which were unilateral. The average age was 13½ years, the youngest being three months, the oldest 30 years. Acquired syphilis was proved in almost 50 per cent. of the cases. Haltenhoff[4] cites 72 private cases of interstitial keratitis and concludes that more than half were due to hereditary syphilis. Five were due to the acquired disease. The disease in question is certainly a rather rare one, but it may be as Valude says, the small number of cases on record is due to the neglect of observers to examine young patients for the signs of acquired syphilis.

While, naturally, most of the cases occur in individuals in adult life, it might be found in children who had been infected accidentally, and about whom there might be no suspicion of acquired trouble. Most observers who have described cases of keratitis from acquired syphilis have found it develop as a late secondary or as a tertiary manifestation.

Lawford[5] describes one case in which keratitis developed four and a half months after the primary lesion, and another in which eleven months elapsed between the primary sore and the keratitis.

Trousseau[6] has observed 11 such cases, 8 of whom were females, 3 males. The keratitis occurred in the second or third year after the infection, and in most of them only one eye was affected. Hutchinson records a severe case in which the keratitis was simultaneous with the secondary eruption and sore throat.

Lang[7] cites the case of a man who developed interstitial keratitis 12 years after infection. Trousseau and Trantas[8] believe that keratitis from acquired syphilis is not so rare as is commonly supposed, and report a case that occurred thirteen years after the primary disease.

The clinical features of acquired syphilitic keratitis vary. Different writers have described cases of diffuse interstitial keratitis differing in no essential particulars from the lesion as seen in inherited syphilis, except that it is more frequently unilateral, and the degree of vascularization is much less. Iritis may or may not be associated with this form.

More distinctive, however, is the form in which the lesion develops at some point of the corneal circumference as a rather dense grayish infiltration which remains limited to this part of the cornea passing through all its phases with no tendency to ulceration. Sometimes, as illustrated in Case 1, the dense opalescent opacity may extend quite up to the margin of the cornea and appear to be merged in the sclerotic; in other cases there may be a clear space between the site of the lesion and the limbus. In this form of the disease vascularization is not a prominent feature and is absent in most of them. This point is emphasized by Boucheron, Terson, Chevallereau and others. Irido-cyclitis and choroiditis may be associated with this condition, so that this form may be the same as that described by Mauthner[9] and Antonelli[10] under the name of "keratitis interstitialis punctata."

The reports of the cases of most observers do not show that there was much disturbance of the epithelium; on the contrary, many of them dwell upon this point and contrast it with the steamy condition of the cornea as seen in the interstitial keratitis of inherited syphilis.

In the third case reported there were two distinct vesicles on the cornea that were over the spots of infiltra-

tion. These probably ruptured, but no ulceration followed. Finally, in very rare cases gumma of the cornea may exist. It seems, therefore, that the following conclusions are justifiable: There is such a lesion as syphilitic keratitis occurring at any time from the early secondary to the late tertiary period of syphilis. The disease is milder and shorter in its course than the keratitis from inherited lues. It usually affects one eye rather than both. It may assume either the diffuse or punctate forms and may or may not be associated with uveitis. Its most characteristic form is that in which there is a large dense infiltration, with little or no vascularization and no tendency to ulceration and no iritic complications.

It causes less injury to the cornea because, being more amenable to treatment, the infiltrate is removed before it forms permanent opacities. Active antisyphilitic treatment is most useful in shortening the course of the disease, whereas in the inherited form such treatment accomplishes little.

103 State Street.

DISCUSSION.

DR. S. D. RISLEY, Philadelphia—In my experience corneal disease due to acquired syphilis has been extremely rare. When disease involving the deeper layers of the cornea was observed among the secondary or tertiary manifestations of syphilis is was usually in broken-down patients, and presented much the same characteristics as we are accustomed to witness in illy-nourished and strumous patients. I have seen many examples of serpiginous ulcers involving the limbus of the cornea in colored people the subject of other syphilitic phenomena, but it has not been clear in my own mind whether to ascribe these to the direct influence of the syphilitic poison or to the indirect impairment of the general nutrition of all the tissues. I have seen much more frequently affections of the membrane of Descemet occurring in association with general uveitis in syphilitic people. This is of interest as demonstrating the correctness of those anatomic studies which from the standpoint of embryology regard the lining of the anterior chamber as a modified continuation of the uveal tract. In these cases Kneis has pointed out that the endothelial lining of the cornea suffers a solution of its continuity and the underlying portions of the cornea become involved in the disease. I regard it as quite remarkable that the cornea is not more frequently involved in more obvious manifestations of acquired syphilitic lesions. Since syphilis is so frequent, in the colored race especially, it is always to be borne in mind that in any case of acquired syphilis there may be an hereditary taint also, which might account in some instances at least for the occurrence of the corneal disease.

LACHRYMAL STENOSIS IN INFANTS AND ITS TREATMENT.*

DUNBAR ROY, A.B., M.D.

Clinical Professor of Eye, Ear, Nose and Throat Diseases, in the Atlanta College of Physicians and Surgeons; Fellow of the American Laryngological, Rhinological and Otological Society, Associate Member of the American Ophthalmological Society, Etc.

ATLANTA.

If one will examine the various text-books on ophthalmology, he will be unable to find any reference to the subject of the treatment of lachrymal stenosis in infants. The conclusion therefore derived is, that such a condition in infants is treated in the same manner as in adults. This I consider erroneous teaching. Very grave injury would frequently be done to the lachrymal passages of these tender little individuals if the same ruthless probing and cutting were done as is frequently the case among adults. During the last four years of my practice, I have had six cases of lachrymal stenosis in infants, all of which recovered perfectly without instrumental interference, and one case presented some such striking features, whether as a coincident or as a causal relationship I do not know, that I shall take the liberty of referring to it more in detail. In speaking of lachrymal stenosis in infants we must naturally do so in a very indefinite manner, not knowing whether the stenosis is in the puncta lachrymalia, the canaliculi, lachrymal sac or in the duct proper. This could only be determined by delicate probing or postmortem demonstrations, both of which methods being often impracticable. When we speak of lachrymal stenosis in infants we naturally mean such cases as present the usual accompanying symptoms of excess of tears in the conjunctival sac or even flowing out upon the cheek, some excoriations of the lower lid, and some slight catarrhal condition of the palpebral conjunctiva. There need not have been previously a dacryocystitis either acute or chronic.

The well-known fact that the mucous membrane in infants is so susceptible to swellings and edematous conditions, will in a great measure account for the stenosis occurring in individuals of this age. Yet such pathologic conditions do not constitute the whole etiologic factor in these cases.

For convenience I have made the following groupings of lachrymal stenoses occurring in infants.

1. Stenosis due to Congenital Malformations and non-development in some Portions of the Lachrymal Passages.—Cases of congenital malformation in some portion of the lachrymal passages have been reported by several observers and the presence of such must not be ignored when cases of epiphora in infants are brought to us for treatment. Congenital absence of one or more puncta lachrymalia have been noted by various writers.

Benjamin Travers,[1] as early as 1824, says in his book on "Diseases of the Eye," that he had seen a congenital deficiency of the puncta, but the case was very rare, obliteration being much less so. Schon[2] in 1828 noted the fact that puncta had been observed closed entirely in new-born infants, and cites two or three authors who mention the condition or had seen cases. V. Walther[3] states that congenital atresia of the puncta does not occur except in connection with monopsia or micropsia; and Desmarres[4] states that Seiler, Schoen, Carron and others have noted congenital atresia of the puncta mostly in connection with concomitant absence of the eye. The congenital absence, however, of these puncta have been observed by others who make no mention of any other congenital defect. Mooren,[5] in a statistics of 108,416 patients, gives only one instance of "defectus punctorum lachrymalium."

In our own country, a case has been reported by Burnett[6] where there was congenital absence of both puncta lachrymalia of the left eye and of the lower punctum of the right eye. The case terminated successfully under operation. Theobald[7] has also reported a case of congenital atresia of one lower punctum. Besides these, cases of congenital atresia or absence of puncta have also been reported by Zehender,[8] Vossius,[9] Fieuzal,[10] Emmert,[11] and Blanchet.[13]

Cases have been reported where the puncta were not absent but only closed by a membrane. Le Henoff[14] calls attention to this condition, claiming that it is

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

not rare in infants to find a small pellicle covering the opening of the puncta.

A. Rochon-Duvignaud,[15] in a very exhaustive article, gives the results of his researches on the anatomy and pathology of the lachrymal passages in the adult and the new-born. According to this observer, in the fetus the nasal duct, up to a certain period, is separated from the nasal fossa by a membrane. The duct also exhibits annular diaphragms or valves at various points along its course; these diaphragms were found by the author in the new-born in more than half the cases. Persistence of a nearly imperforate membrane closing the lower end of the nasal duct, or the presence of diaphragms with only a minute passage through them, is a cause of stenosis in infants, especially when from the stagnation and accumulation of the secretions, infection, inflammation and swelling of the mucosa result. Bochdalek,[16] as early as 1866, in a contribution to the anatomy of the lachrymal organs, calls attention to the fact that in extremely rare cases the inferior valvule of the lachrymal sac develops so as to form a nearly imperforate thin membrane closing the canal. He mentions two cases where this condition existed.

The presence of these valves, especially at the junction of the sac with the lachrymal canal, and the junction of this latter with the nasal fossæ, are considered by many to play the most important rôle in the stenosis found in infants. For instance, Beraud[17] in his researches states that a valve at the junction of the nasal duct and nasal fossa, is missing in only 3 or 4 per cent. of cases, and he found complete obliteration of this orifice in 15 per cent. of the cases of lachrymal stenosis. He also states that the so-called valvule of Taillefer, situated about the middle of the nasal canal, is present in about 6 per cent. of cases and may be so developed as to close the canal.

2. Lachrymal Stenosis occurring as the result of Spasmodic Contraction in some Portion of the Passages.—Allow me briefly to relate a case which occurred in my practice more than a year ago: Master B., aged 2 months, was brought to my office for consultation on account of an epiphora of both eyes. On examination I found a slight catarrhal conjunctivitis, while the puncta were freely open. The condition had been noticeable for three weeks past. No discharge could be pressed from the lachrymal sac. A wash was given for the eye, consisting of sulphate of zinc, boric acid and water, to be used three times daily and to be accompanied with pressure over the lachrymal sac. This was continued for three weeks with no very decided improvement in the condition. About this time the father noticed that the infant seemed very fretful and on consulting his family physician it was decided to have the infant circumcised. This was accordingly done and an immediate cessation of the epiphora was noticed which has continued constantly ever since. I then began to look up the literature to see if I could find a similar case. This I have been unable to do. The relationship between the circumcision and the cessation of the lachrymal symptoms was so close that I can not but consider it in the light of cause and effect.

In looking up the literature of the subject, I find that there is some reference to spasmodic constriction of the lachrymal passages as a cause of stenosis. In the Transactions of the French Ophthalmological Society for 1891,[18] Galezowski states that epiphora often occurs from spasmodic or irritative muscular contraction of the lachrymal passages without any organic changes being present. Wicherkiewiz, at the same meeting, corroborated Galezwoski's observation as to the occurrence of spasmodic strictures. Seggel,[19] in quite an elaborate article, calls attention to the presence of muscular tissue around the canaliculi and puncta, and reports a case of stenosis which he said was due to contraction of the spinchter of the punctum. It is the atrophic condition of this sphincter, in my judgment, which is the frequent cause of "watery eyes" seen in the very aged.

R. Schirmer,[20] in "Saemisch. Handbuch," says that spastic constrictions of the canaliculi may occur (as shown by McNamara and Galezwoski) in nervous and anemic persons and in this way produce the same disturbances as other obstructions. McNamara,[21] in his work upon the eye, mentions briefly spasmodic stricture of the canaliculus, which occurs either at the inner or outer opening of the canal. The accompanying watery eye, if long continued, will be of intermittent character.

Fano[22] calls attention to the existence of spasmodic epiphora due to spasmodic constriction of the lachrymal puncta and canaliculi by spasm of the muscles of Horner. The condition occurs only in women of nervous temperament, often in association with neuralgias. Since the occurrence of this case in my own practice, I am firmly convinced that we should look more carefully into conditions which might act as a reflex cause in producing this spasmodic constriction in the lachrymal passages. Observation teaches us that epiphora in infants sometimes disappears in a night, and in such cases may we not attribute this result to a relaxation of a spasmodic constriction?

3. Stenosis, the Result of a Catarrhal Thickening of the Mucous Membrane at some Point in the Lachrymal Passages.—This third and last consideration of stenosis I would place as the most frequent cause of epiphora in infants. In the cases which I have seen there was a slight catarrhal conjunctivitis which was either primary or secondary to a similar condition in the lachrymal passages. In only one instance could secretion be expressed from the lachrymal sac. In two instances there was a marked catarrhal condition of the nasal cavities. This latter organ should always be closely examined in such cases.

A. Peters,[23] of Bonn, has reported seven cases of lachrymal stenosis in infants due to a catarrhal condition of the mucosa of the lachrymal sac. He believes that blennorrhea of the lachrymal sac in new-born infants is caused by the persistence of the fetal membrane closing the lower end of the nasal duct. Fluid accumulates in the sac, the product of cellular disintegration and secretion from the mucosa of the sac, rather than derived as an inflammatory exudate from catarrh of the mucous membrane. The condition is one of atresia and retention and not catarrhal inflammation.

He recommends simple treatment—expression of the contents of the sac by digital pressure and repeated irrigation of the eye without the use of the knife or probe. He quotes Vossius and certain French authorities in favor of gentle treatment. He strongly urges this palliative treatment in preference to any instrumental applications.

In support of Peter's theory, Lange[24] reports a case of blennorrhea of the lachrymal sac in a child five days old. Pressure upon the sac was followed by a discharge of laudable pus from the nasal cavity of the same side, but none came from the lachrymal canals. All symptoms of lachrymal obstruction disappeared in a few days. Heddaeus[25] confirms the observations of

Peters, but differs from him in thinking that the mechanical expression of the contents of the sac is unnecessary. Konigshofer,[26] in discussing the epiphora in children, says that dacryocystitis or dacryostasis neonatorum, according to his observation, is mostly a temporary blocking of the passages by mucus or a persistence of a thin epithelial closure of the nasal end of the duct. All cases observed by him were cured by industrious expression of the lachrymal sac, a passage of the sound being necessary in only one case. Landolt,[27] in treating of obstructions in the lachrymal passages of new-born, has this to say in regard to the treatment; according to his observations it is never necessary to slit the puncta. He dilates the punctum with a conical sound and injects either a bichlorid solution 1 to 5000, or 10 per cent. solution of boric acid into the sac with an Anel's syringe.

Before writing this article and after consulting the various works on ophthalmology to see what the authors had to say in regard to epiphora in infants, I addressed letters to twelve ophthalmologists and asked them to answer the following questions:

1. Have you ever seen any case of stenosis of the lachrymal passages in infants which you thought was due to spasmodic contraction, the result of a reflex irritation?

2. What treatment do you use for lachrymal stenosis in infants?

To these letters I received seven replies, as follows:

Dr. H. Knapp: 1. No. 2. I leave the lachrymal trouble alone, as it commonly rectifies itself by the development of the nose.

Dr. E. Gruening: 1. I can not recall a case of stenosis of the lachrymal passages, either in infants or adults, due to spasmodic contraction. 2. In cases of lachrymal stenosis in children I probe under ether, using Theobald's probes.

Dr. William Cheatham: 1. No. 2. I have seen, I think, as many as five cases of stenosis of the lachrymal duct in infants, all relieved by from one to three probings with Bowman's No. 1, without incision of the punctum.

Dr. Swan Burnett: 1. I have never seen a case of stenosis of the lachrymal passages in an infant which I thought was due to spasmodic contraction. 2. The few cases of dacryocystitis in infants that I have seen, I have treated in the usual way by opening the canals and treating the sac. I don't remember that I ever saw a case of stenosis not due to inflammation.

Dr. Adolph Alt: 1. I do not remember having ever seen a stenosis of the lachrymal passages in infants which I thought was due to reflex contraction. 2. The cases of stoppage in infants, if not due to an infection of the mucous membrane of the drainage apparatus, I have always referred to an epithelial adhesion and this usually gave way to one or two probings.

Dr. George de Schweinitz: I have never seen a case of stenosis of the lachrymal passages in an infant which I thought was due to a spasmodic contraction, the result of reflex irritation. 2. The treatment I use for lachrymal stenosis in infants depends entirely upon the etiology. Many of the cases get well without any treatment except some irrigation of the conjunctival sac and nares; they get well simply because in the development of the nose a pre-existing contraction of the passages disappears. Others, evidently dependent upon a nasal catarrh in the broadest acceptation of the term, get well by nasal treatment. A few with a good deal of purulent secretion are associated with stricture and seem to me to demand the same treatment that a similar condition in adults requires. I very rarely, however, and I have seen a good many cases, have found it necessary to divide the canaliculus and pass probes.

Dr. Samuel Theobald: 1. No. 2. I have met with a good many cases of blennorrhea of the lachrymal sac in infants accompanied with epiphora. In most of these cases there was not an actual stricture of the duct (such as we meet with usually in adults), and they have gotten well without operative interference. My favorite remedy is a collyrium of hydrarg. bichlorid 1/24 gr., sodium chlorid 3 grs. to ounce of water. This to be dropped into the inner corner of the eye three times daily, each application to be preceded by an attempt to empty the lachrymal sac by pressure with the finger tip. Occasionally it happens that no benefit results from this treatment. Then after it has been thoroughly tested for some weeks, I resort to operation, slitting the canaliculus and probing the duct.

In all of my cases a cure was established by the use of an astringent wash to the conjunctiva in conjunction with massage over the lachrymal sac. In no instance was a probe used. I can imagine some cases where it is necessary to dilate the canaliculi with a probe, but never a case where it is necessary to slit the canaliculi and pass probes into the nasal duct. Palliative measures, such as the use of astringent washes, accompanied by massage over the lachrymal sac, will accomplish the necessary result in all but exceptional cases, even if the treatment has to be continued for many weeks. I believe that the canaliculus should never be slit and thus destroying forever the contractile effect of the sphincter around the puncta. At the same time it is necessary to see that there is no blocking of the nasal passages with inspissated mucus. Cleansing of the nasal passages should be as routine as the cleansing of the eye. I am firmly convinced that many cases of epiphora in infants will be relieved if more judicious attention is given to the nasal cavities.

Sugar as a Stimulant for Muscular Exertion.—Lop states in the *Gaz. des Hop.*, 120, that the midwives in the south of France have long administered sugar as a means of combating inertia of the uterus.

A STUDY OF A FETAL STOMACH,

WITH SPECIAL REFERENCE TO THE ORIGIN OF ACID SECRETING CELLS.*

W. A. EVANS, M.S., M.D., AND WILHELM BECKER, M.D.
CHICAGO.

This specimen was examined with a view to determining the origin of the acid cells. It is proper to begin by considering the origin of the hydrochloric acid. We assume that the works of Wesener and others have demonstrated that the acid is derived not from the food, but from the cells of the stomach wall.

Assuming then that it is proven that the acid is secreted, we pass to the question as to whether the acid is in combination with the ferment. A review of the literature convinces us that there is a loose chemical combination between them. Where is this combination effected? Is it in the same cell, or are there different sets of cells—one secreting ferments, another acid. Again, we conclude that there are different cells.

If there is a division of function, which cells are secreting acid, and, as a subsidiary proposition, whence are these cells derived? The method of distinction that we have used are the tinctorial procedures.

It is proper to determine the value of such methods. Ehrlich's holding was that the reaction of the different portions of cell protoplasm could be rather easily distinguished by their staining peculiarities. For example, if chromatin filaments stain with a basic stain, it was proof that those filaments were acid in reaction. The work of Mathews would tend to upset these ideas.

Mathews found that while cytoplasm albumin usually stains with an acid stain, and is therefore alkaline in reaction according to Ehrlich, it will stain with a basic stain, if it is in an alkaline solution, and that in slightly acid or neutral solutions the basic dyes will stain any element of the tissue which contains an organic acid in salt combination with a strong base. The basic dyes in alkaline solution may thus be used for the detection of albumins in the cell and especially of all albumins possessing a phenol or tyrosin group. In no sense are the basic dyes a test for nucleic acid or chromatin. As to the acid stains, he says the acid stains enter into chemical combination with the albumin molecule in protoplasm and probably with an NH_2 group in that molecule.

Silenfeld showed that protoplasm would stain with an acid stain if its nucleic acid was saturated with albumin. If the nucleic acid was not wholly saturated it would stain with a basic dye.

The conclusions that we are entitled to draw are that the question of staining is more complicated than Ehrlich must have thought, and that there is more to the subject than the reaction of tissue and the stain. Nowhere is this seen better illustrated than in the stomach cells.

The labors of Stinzing, Heidenhain and others have shown that free or loosely combined mineral acid in a protoplasm does not cause that protoplasm to stain with a basic stain. If Ehrlich's position were right, then the protoplasm of the acid cells should stain with a basic stain, and we could, therefore, always pick them out with great ease. We are not able to distinguish them with this simplicity and ease. Nevertheless there are stains that pick out what are called acid cells with fair clearness.

The sections examined by us were stained by Stintszing, Ehrlich, Biondi-Heidenhain, hematoxylin-erythrosin-acid fuchsin, Romanowsky's alkaline methylene blue and eosin stain, thionin, polychrome methylene blue, toluidin blue, and hematoxylin-eosin. What seemed a specific tint was given by the hematoxylin-eosin stain, the hematoxylin-erythrosin-acid fuchsin and the polychrome methylene blue.

In these sections we notice that the acid cells appear as large masses of granular protoplasm with several vesicular nuclei. These nuclei have a moderate number of nodal points. The protoplasm of the cells shows no trace of lines of division or incomplete fusion. The protoplasm otherwise shows no evidence of degeneration. The nuclei show no degeneration phenomena. With the Stintzing stain, the yellowish-red color of these cells differs from the tint of any other of the stomach cells. It is just the same shade as that noted by us in the supposed acid cells of the actively secreting stomach of a dog. These cells are frequently between the principal cells and the muscularis mucosa; frequently,

Fig. 1.—*a*, Masses of so-called acid cells; *b*, gland tubes; *c*, inner circular muscle; *d*, outer longitudinal muscle.
Leitz, Eye piece 3, Ob. 4.

however, they are well below the muscularis mucosa, in the submucosa.

Are they derived from the principal cells, from preexisting acid cells, from the ordinary submucosa cells, or from the special cells in the submucosa?

Neumeister speaks of the "wandered off" cells of the lumen of the glands. We are not certain, yet we think he means that they have wandered from the principal cells to the muscularis mucosa or even underneath. He does not demonstrate the point that he speaks of by any illustration. Carlier refers to the acid cells as oxyntic cells. He does not say where they originate.

Might these cells not be derived from the submucosa? We can not make out any transition cells between the principal cells and these, either as to outline, staining peculiarities, general appearance or location. It is true that glands were just beginning to develop in this organ, but if these are glands we ought to see some evidence of down-growing and indenting of the muscularis mucosa. This is not seen in this specimen. The cells in the underlying tissue are without any indication of a more superficial origin. The possibility that these are epi-

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Pathology and Bacteriology, and approved for publication by the Executive Committee: Drs. A. Stengel, W. S. Hall and L. Hektoen.

thelial cells does not constitute a barrier to their origin in the submucosa. The work of Leo Loeb shows that cells are in some measure transformable; that the old blastic divisions are not unchangeable.

As to the origin of the acid cells I quote the following: "Stintzing believes that acid cells are changed into chief or pepsin cells. Breemner believed that the acid cells were expelled with each digestive act. Heidenhain says that this has been disproven. Herendorfer believed that the parietal cells developed into the principal cells. Edinger believes that the parietal cells develop from the principal cells. Orth agrees with Edinger. Toldt and Storler believe the relation to be just the reverse. Nueikler believes them to be of the same origin." It is well to know, however, that the major part of this work was done in the olden times when the cells were supposed to stick closer to their blastic fellows than we now think; when structural methods were scarcely as complete, and when our knowledge of the cells, usually situated in connective tissue, was not so great as that of to-day.

We have no opinion to offer as to the origin of these

Fig. 2.—*a*, So-called acid cells; *b*, stomach gland. Leitz, Eye piece 3, 1/12 oil.

cells. Whether from the epithelium wandering occasionally into the deeper tissues, or from the mesoblastic elements wandering frequently into the epithelial zones we do not say. We merely call attention to certain cells sometimes in the mucosa and sometimes in the submucosa which contain a single vesicular nucleus, generally centrally placed and with a large amount of cytoplasm, this cytoplasm having coarse granules that stain with acid stains to just the same shade as the acid cells of the stomach tubules.

What proof have we that these border cells are specific, differing from the more universally recognized ferment cells? We note the following points: The location of the cells are sometimes in the deeper epithelial structures, sometimes in the muscularis mucosa, sometimes in the submucosa; the principal cells are always in the one place; the coarse granules stain a peculiar shade with every stain employed, a shade not seen anywhere in the principal cells; the basic third of the principal cells are granular, but their shade is not the same as in the border cells. The nearest approximation to this shade is in the material found adhering to the free surface of the stomach mucosa. Thiohari speaks of the differences in shade, size and distribution of the granules in these two kinds of cells. He says that in the border cells there is an outside zone of coarse staining granules, and that these seemed to form the only cell wall. It was also noted that internal to this the granules seemed to be in small groups of two to five. There were large protoplasmic masses, often triangular in shape and with several oval or spindle or semmel shaped, vesicular, nodal nuclei. This shape in no way resembles the long, narrow, principal cell, with its clear or faintly granular outer third and its basic third with its mixed basic and faintly acid granules.

In our specimen we found no peri-nuclear, clear vacuoles, as described by Hambergher; but we are to remember that Hambergher only observed these after some hours of digestion.

We find these cells most abundant in the cardiac end, and wholly absent in the pyloric end. We find them occasionally quite removed from the principal cells. These were our reasons for believing the two cells to be of a different nature and probably different in function.

Carlier and Thiohari both believe in separate acid cells. Our specimens would not indicate that the hydrochloric acid exists in the oxintic cells as hydrochloric acid. On the contrary, their method of staining would indicate fairly clearly that within the protoplasm the hydrochloric acid is not only satisfied by albumin or some other base, but that that base still had some basic bonds with acid affinities. It must leave the cell as some easily decomposed compound, which, as Carlier outlines, gives its acid to zymogen to form zymin.

NOTES ON THE INTRACELLULAR OCCURRENCE OF DIPLOCOCCUS PNEUMONIÆ IN CEREBROSPINAL MENINGITIS.*

LOUIS BLANCHARD WILSON, M.D.

Senior Demonstrator in Pathology, University of Minnesota; First Assistant Bacteriologist, Minnesota State Board of Health.

MINNEAPOLIS.

That the diplococcus pneumoniæ, in common with other micro-organisms, may occasionally be found within leucocytes as the result of phagocytosis in inflammatory processes, has been frequently noted by numerous observers. Its extracellular position, however, in the exudate in cerebrospinal meningitis is so markedly the rule that the point is used as a differential characteristic between the organism and diplococcus intracellularis meningitidis. Consequently, the preponderatingly intracellular position of diplococcus pneumoniæ in the following four cases of cerebrospinal meningitis makes them of sufficient interest to warrant their record.

Case 1.—In June, 1898, a specimen of cerebro-spinal fluid from a case of cerebrospinal meningitis, removed by lumbar puncture during the third week of the disease, showed in direct cover-slip preparations, numerous encapsulated, lanceolate, Gram-staining diplococci, most of which were intracellular. Cultures in broth, on plain and blood agar, and Löffler's blood serum developed, without admixture of other organisms, a diplococcus, which, despite its original intracellular position, was readily identified as diplococcus pneumoniæ. Unfortunately, no animal inoculations were made, since the pressure of other work prevented it until the cultures

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Pathology and Bacteriology, and approved for publication by the Executive Committee: Drs. A. Stengel, W. S. Hall and L. Hektoen.

had died out. The patient died two days after the specimen was taken, but no autopsy was obtainable.

CASE 2.—Two months later specimens from this case were obtained. The materials for this examination, consisting of the left frontal and parietal lobes, cerebellum, pons, and medulla of a child, were received in the laboratory Aug. 25, 1898, at 11 a. m. The attending physician, Dr. George D. Head, has kindly furnished the following clinical and autopsy notes:

Baby S., an inmate of the Children's Home, age 7 months, was well from birth, except a few superficial abscesses present some time in June or July. Became sick Aug. 19, 1898. Child was dull, restless and refused food. Passed several foul stools, which were pus-like in appearance, but, which on microscopic examination, showed no pus; these were simply masses of bacteria. Temperature 102. All other symptoms negative. Diagnosed enterocolitis.

August 20: Child is brighter and takes food; moves head from side to side; puts left hand to head as if to wipe away some object; temperature 101; some stupor later in the day; bowels do not move so often as on previous day.

August 21: Temperature 99½; stupor continued; takes food. Stools more normal; peculiar ashen hue about face, which indicates profound infection.

August 22: Temperature 101; no other change.

August 23: Temperature 101; takes some food; duller and very quiet.

August 24: Temperature 102; child restless; diagnosed meningitis.

August 25: Temperature 103; stupor; general condition of child worse.

August 26: Child dead in the morning at 2 a. m.; no convulsions.

An autopsy was held 7 hours after death. A complete examination was made, and all organs except the central nervous system were apparently normal. Over the entire convexity of both cerebrum and cerebellum was a gelatinous exudate, filling the pia and extending, though in smaller quantity, over the base of the brain. Portions of the brain and medulla were placed in a clean jar, which had just been washed out several times with boiled water, and taken immediately to the laboratory.

When the specimens were received in the laboratory, cover-slip preparations were made direct from the exudate and cultures from the same source were sown on serum, glycerin agar and in glucose glycerin broth. Specimens were then divided into small pieces and portions of each placed—nine hours after death—in 96 per cent. alcohol and in 10 per cent. formalin solution.

Direct cover-slip preparations stained by eosin and methylene blue and by Gram-Bismarck brown, showed numerous lanceolate and occasional encapsulated diplococci, sometimes outside of, but more frequently definitely within, polymorphonuclear leucocytes. These diplococci retained Gram's stain with great tenacity.

Cultures on serum and agar, after 24 hours in the incubator, showed few small, pin-point, moist-appearing colonies, which, when examined in stained cover-slip preparations, were found to be composed of diplococci, which retained the stain by Gram's method.

Cover-slip preparations from the broth cultures showed lanceolate diplococci in single pairs and in chains consisting of from two to eight pairs each. These retained the stain by Gram's method. The organism was sown on the following culture media with the results noted: Glucose glycerin broth gave a very faint growth and no precipitate; plain broth, a very faint growth and no precipitate; litmus milk, after two days, faintly acidified and slightly coagulated. Plain agar gave a scant growth, otherwise like glycerin agar (see above). Glycerin agar was characteristic as noted above. Litmus lactose agar, after 24 hours, showed colonies similar to those on glycerin agar, and medium slightly reddened.

Löffler's blood serum was characteristic as noted.

Parallel cultures of diplococcus intracellularis meningitidis were made at the same time and on the same media, the specimen having been isolated two days previously from an acute case of meningitis in a child. The cultures of the two micro-organisms were sufficiently unlike, so that, aside from their morphologic and staining characteristics, there was little difficulty in differentiating them.

The tissues fixed in 96 per cent. alcohol and in 10 per cent. formalin were further hardened, embedded in parrafin and cut five, ten and twenty microns thick and stained with hematoxylin and eosin, Gram-Bismarck brown, eosin-Unna and by Nissl's method. They presented nothing aside from what is ordinarily found in cases of intense, acute meningitis, except those stained by Gram-Bismarck brown and Gram-eosin. Here in the subpial exudate and also scattered in sections of vessels throughout the tissue, are great numbers of Gram-staining lanceolate, frequently encapsulated diplococci. These are most frequently lodged within leucocytes. Many cells contain from one to twelve cocci each. The cells nearest the arachnoid—those best preserved—nearly all contain diplococci. The fibrinous mass nearest the brain substance contains a few intact leucocytes, some of which are literally stuffed with diplococci. Numerous isolated pairs of diplococci are seen in the vacuoles within the brain. None are observed within the nerve cells proper and none are present in the vessels except rarely in leucocytes, apparently within the vessel walls.

3. CASES IN HORSES.—In June, 1899, specimens were collected from two horses, killed, when almost dead, for purpose of autopsy during an outbreak of meningitis near Herman, Minn. These animals had been sick but a few days. At the autopsy very perfect gross lesions of meningitis were present in the brain and cord. The cases presented nothing of unusual interest other than that direct cover-slip preparations and sections showed numerous Gram-staining, lanceolate, frequently encapsulated diplococci, which were more frequently intracellular than extracellular.

Cultures obtained without admixture of other organisms from both cases showed typical diplococcus pneumoniæ of unusually abundant growth. Twenty-four hour colonies on rabbit's blood agar and Löffler's serum occasionally almost equaled in diameter colonies from parallel sowings of diplococcus intracellularis isolated from a case in a young man three days previously. The cultures from these cases of equine meningitis were inoculated alternately subdurally and intravenously, into six rabbits. These animals all died of meningitis in from twenty-four hours to four days with marked symptoms and typical lesions of meningitis.

From the central nervous system of each of the rabbits direct cover-slip preparations showed numerous diplococci, morphologically identical with those in the original preparations and more frequently intracellular than otherwise. The experiments were continued by the inoculation subdurally of a horse with 10 c.c. of an emulsion of a twenty-four hour, plain, broth culture, fourth series from original horse, with five twenty-four hour original serum cultures from the brains of two of the six rabbits mentioned above. Sixty hours after the inoculation the animal died, and an autopsy was made at once, which revealed typical meningitis, very intense in

character. Direct cover-slip preparations, and, later, sections showed enormous numbers of diplococci, morphologically like those in the original material, and in most instances, contained within cells.

It may perhaps be worth noting that in all of the cases, two human beings, three horses naturally infected, six rabbits and one horse inoculated, the organism appeared to be particularly virulent.

These instances serve to show that it is possible occasionally for diplococcus pneumoniæ to occur abundantly within the cells of the exudate in meningitis. This may indicate a closer relation than is ordinarily supposed to exist between diplococcus pneumoniæ and diplococcus intracellularis meningitidis. The point certainly merits further investigation.

The position of the coccus relative to the cell is occasionally of less importance than its shape, arrangement, staining reactions or cultural characteristics. Pathogenesis in all its phases as yet has been insufficiently studied to be of much help in differentiating these microorganisms. It would certainly appear that great care must be exercised in diagnosing, from direct cover-slip preparations of meningeal exudates, between diplococcus pneumoniæ and diplococcus intracellularis meningitidis.

DISCUSSION.

Dr. Hall—I would like to ask Dr. Wilson if he has ever encountered a tendency on the part of the diplococcus pneumoniæ to enter the cells in clinical pneumonia. It seems to me that besides its habit of entering leucocytes in cases of meningitis it also shows the same tendency in organs of a different character like the lungs, etc.

Dr. Wilson—I have observed just this point in cases of pneumonia, though in less degree than in these cases of meningitis. I think the occurrence in pneumonia has been reported previously by a number of other observers.

SMALLPOX AND VACCINATION,

WITH SPECIAL REFERENCE TO GLYCERINATED LYMPH.

GEORGE DOCK, A.M., M.D.
PROFESSOR OF MEDICINE, UNIVERSITY OF MICHIGAN.
ANN ARBOR, MICH.

For three years smallpox has existed in the United States to an extent not generally appreciated. The "Public Health Reports" of the Marine-Hospital Service give a total of 12,947 cases in various states and territories from June 28 to Oct. 25, 1901, and this is not a complete report for the whole country. In Michigan, according to Dr. H. B. Baker, there have been more than 3000 cases so far this year, while the prospect for the future is suggested by the fact that new foci are discovered at a rapidly increasing rate. Most of the cases have been mild, and this fact goes far to explain the great spread of the disease. It has often been so mild that it attracted little or no attention, or, if seen by a physician, was thought to be something other than smallpox; hence the numerous and often absurd names given, such as Cuban itch, cedar itch, etc. Similar conditions prevail whenever a disease otherwise rare breaks out with anything but the most schematic features. Often, perhaps most frequently, inadequate steps have been taken to clear up the nature of cases or epidemics. More than once I have known of health officers deciding that certain cases of mild smallpox were chicken-pox, forgetful of the numerous examples of the danger of an offhand decision in a matter so often difficult. One can readily forgive the mistake in diagnosis, for a case of smallpox, when seen only once, may easily be impossible to recognize, and in some cases a positive diagnosis may never be possible. But, as it is well known that some other diseases, such as chicken-pox in the adult, may present a similar difficulty, the only safe way is to take precautions suitable for the more serious disease, whenever the question arises. Failure to take this simple step, and, still worse, fixed belief in a faulty diagnosis based on incomplete examination, have had much to do with the present epidemic.

We must not forget that, even if mild, the epidemic has a very important significance. Though a mortality of 3.2 per cent., as in the four months cited, seems too small for consideration as a smallpox death rate, it assumes another aspect when we realize that it involves the deaths of 416 people. Nor is the mortality uniformly low. Dr. O. J. Porter[1] tells us that in his field of observation in Tennessee all of five or six hemorrhagic cases died, 40 per cent. of confluent cases, and 10 to 15 per cent. of discrete. Moreover, a smallpox epidemic has other evil consequences besides deaths. The general alarm and private worry; the interruption to business, often leading to personal violence or hardship; the quarantining of cities; and last, but not least, the injury from hurried vaccination—all these raise what is often called mild smallpox to the dignity of a serious epidemic. Even if none of these objections existed, the wide extent of such a disease reflects just as severely on our civilization as if we had so much itch or plica Polonica.

Epidemics of smallpox, whether mild or severe, always indicate the concurrence of a number of avoidable causes, the most important of which are lack of general hygiene, failure of special precautions with single cases, and the existence of a large number of unprotected people. The latter may result either from total failure to vaccinate, or from the use of imperfect lymph. Total lack of vaccination is a more important cause, in many places, than we are perhaps aware. Out of a large number of adult patients admitted to the University Hospital from all parts of Michigan, only 60 per cent. had scars from previous vaccination, and a considerable proportion of these were from sores so badly infected as to make the immunity a matter of grave doubt. Many suppose that, although we have not compulsory vaccination, voluntary vaccination is carried to as wide a degree as is necessary. This is evidently a most illusory view.

But I wish at this time to speak of inefficient vaccinating material and its place in the spread of smallpox. In strange contrast to the important object, and regardless of the claims vigorously made and as strenuously denied as to results, the operation of vaccination is often made with a carelessness hard to understand. The preparation of the material is left entirely to private enterprise. That much, perhaps most, of it is reliable speaks strongly for the honor and good faith of the makers, who do not claim to be actuated by other than commercial motives. Yet when we see how narrow a line separates legitimate and dishonest pharmacy, so narrow that often the same roof covers both; when we remember the exploitation of fictitious drugs, of short-weight pills and kindred matters, we can not but realize how easy it must be to put forth any kind of virus, knowing it will find a market if sufficiently advertised.

FAILURE OF MEDICAL SCHOOLS TO TEACH VACCINATION.

Not less remarkable is the almost total failure on the part of medical schools to teach the method of vaccina-

1. Johns Hopkins Hospital Bulletin, September, 1901.

tion and the phenomena of the disease so produced. Students very properly spend hours learning how to close a wound of the intestine, yet they may, and often do, graduate without the opportunity of even seeing a demonstration of vaccination. So we find that the operation is often imperfectly done, with no aseptic precautions, and inevitably giving the impression that anyone could do it as well as the physician.

As there is lack of control of vaccine material, so is there of the results, and the logical outcome is the fact that irregular, but legally qualified, practitioners give certificates of satisfactory vaccination without any operation at all.

GLYCERINATED LYMPH.

The history of glycerinated lymph furnishes striking illustrations of errors that have been observed at times since the beginning of vaccination, and I shall ask your attention to some statements regarding it. After the introduction of glycerinated lymph into the United States, I was very early struck by differences in the action of the American product as compared with that used in Europe, a difference that, on several occasions, I have called to the attention of members of the medical profession. The occurrence of a case of smallpox, about a year ago, led to a very extensive vaccination in Ann Arbor. More than 10,000 parcels of material were used, including several makes of dry points and three different kinds of glycerinated lymph in sealed tubes. One of the latter was very satisfactory, and showed all the features of an effective vaccine. Another was even less potent than the subject of the following remarks, but, not being extensively advertised, does not seem worthy of further mention. The third has been widely advertised, very extensively used, and warmly recommended. My personal experience with it, however, had been entirely unsatisfactory, and some other details seem so important that I shall speak of it at some length.

Many months before our smallpox case occurred my colleagues and myself had failed to get good results with this lymph in the primary vaccination of infants. In answer to our complaints the makers first replaced the tubes with some said to be fresher, and, that failing, sent out an agent, who claimed the failures were probably due to faulty technic. He demonstrated the proper method, without disclosing any details unfamiliar to those concerned, and without producing any improvement in the results. In our general vaccination I therefore advised against this particular lymph. This coming to the ears of the makers, the agent visited us again. He explained the later failures as due to overheating of the lymph in the cars, asserted that our experience was quite unusual, and that from all parts of the country no complaints had been received regarding the vaccine. He also arranged to have me see some patients recently vaccinated by an expert, the public vaccinator in the town where the lymph was made.

There I saw lesions like those I had seen before. Some of the vaccinations were primary, others in children who had been vaccinated from one to eight years before. In these, as in the numerous cases in the University Hospital, and in private practice, I could not find a typical Jennerian vesicle. A few small vesicles resembling the Jennerian type developed, but these did not run a typical course. The majority of the lesions, in healthy infants, as well as in unvaccinated and revaccinated adults, were small and conoidal. Sometimes, when large areas had been inoculated, the lesions were large and flatter, but these were made up of clusters of small conoidal masses. The bases of the lesions were red, the upper parts filled with a reddish, or, sometimes, yellowish serum. Sometimes the lesion was a papule of gelatinous appearance, homogeneous or sometimes crowned by a vesicle the size of a pinhead.

A very important point regarding the lesion was the time of its appearance. There was rarely any sign at all by the eighth day, though in some cases minute papules appeared at that time. More frequently it was the tenth or eleventh day, often two weeks, and in some cases three weeks, before any evidence of a "take" was present. The representative of the firm freely admitted this slow development, though he realized the danger of such a feature in vaccinations performed during epidemics.

In the further course the lesions dried on top, forming pale or dark brown scabs. This process was spoken of by the vaccinator and the agent of the firm as umbilication, but a true umbilication I have rarely seen from this lymph. In many cases the scab was very small, the papulo-vesicle remaining for many days in the same state, or slowly shrinking without undergoing proper involution. An areola was not always present, and this fact was claimed by the makers as an evidence of the safety of the virus; but in a number of cases—including 4 out of 31 in the work of the public vaccinator—in persons perfectly well and carefully vaccinated, there was a large areola, and this was often indurated. In the public vaccinator's group one sore was septically infected, as might have been expected among such material. The scabs from the cases I have described fall off at variable periods, and often without leaving permanent scars. I I have yet to see a typical scar from this particular lymph, though in some cases where the wounds became infected secondarily, scars resulted that were looked upon by those interested as evidence of efficient vaccination.

Evidently such lesions as I have described are not new in the history of vaccination. They are not necessarily the results of the glycerin, nor evidences of its beneficial action, but have often been seen and described under various names, following the use of both humanized and bovine lymph, and have always been looked upon as indicating imperfect vaccination and incomplete protection. The evidence of favor of this view is overwhelming. It forms a most interesting chapter in the history of vaccination, but does not seem necessary to review now.

Yet the makers of the lymph have been able to send out an imposing mass of literature in favor of their product, and the claims made, and the number and character of the endorsers, render the matter one of more than passing interest. The medical profession must ultimately be responsible for the quality of remedies and preventive agents used. Here, as in other cases, two things especially have limited the free expression of opinion. One is the lack of a standard, and this can be improved only by more rational instruction. The other is the indisposition to report unfavorably on any substance extensively lauded in advertisements. In the case of the glycerinated lymph I knew from private information that many practitioners and several hospitals had given it up in favor either of other kinds of glycerinated vaccine, or the old-fashioned points. I have since learned that an army medical service, after extensive use of the material, ordered complete revaccination with other virus. Yet apparently few of the disappointed vaccinators sent in complaints to the makers, and the few were easy to offset by testimonials in favor of the material. Recently, objections are coming to

light, and it appears also that the manufacturers have given up the glycerinated virus and now advocate a dry point. If so, the lesson is all the more instructive, for the quiet abandonment of a much lauded and widely used preparation does not tend to stability in practice, nor to faith in medical art. Moreover, no evidence is given that the virus now on the market is better than the glycerinated make of the same firm.

It is useful to examine some of the reports in favor of the glycerinated lymph. Some of them suggest repetitions of reports on other makes of virus, and not actual experience. On the other hand, those who report results in practice have degrees of success so great as to shatter one's credulity in the very beginning. Five hundred primary vaccinations without a failure, even 700 and 800, all successful, are proclaimed. The explanation begins to appear when another "observer" reports "vaccinia sine eruptione," but inasmuch as constitutional symptoms are claimed to be "so slight as to be scarcely noticed" the reader may wish for some of the signs by which the "take" is recognized. Perhaps the key to the puzzle is to be found in one report, in which we find in italics the statement that the writer "sold 13 tubes to a boy living in the infected district and he reported 13 successful vaccinations by himself." Shall we believe the "boy" was an authority on vaccination, or is it not more likely that both boy and professor were ignorant?

An interesting feature in the literature is that while positive statements in regard to the lymph are published, no real proof of its efficacy is given, nor is any explanation offered for the variation in action as compared with other material. The chief point, reiterated many times, is that with the lymph pyogenic infections are never encountered, and these statements are so worded one might almost come to the conclusion that vaccination without severe septic infection had never been seen before.

To be sure, one instance is reported in which the claim is made that exposure to smallpox was rendered harmless by use of the lymph. But in one case the element of chance is always so large that further testimony, with details, is desirable. The continued spread of smallpox should increase cases of apparent protection, as well as of failure, after vaccination with various lymphs, and these should be carefully observed and reported.

In the meantime it might be interesting and instructive to compare the results with those found in other countries, especially in England, where glycerinated lymph was first made widely available, or in Germany, where it is extensively used. The literature on this is not very extensive, but what there is does not tend to prove that such lymph as I have under consideration is trustworthy. It is true that Copeman, in his Milroy Lectures,[2] says the formation of the vesicle is slower than with ordinary lymph, but he also says the "pearl-like Jennerian vesicle appears on the eighth day," and he gives the photograph of a vesicle on the eighth day that leaves nothing to be desired. It is also noteworthy that in Germany those vaccinated with glycerinated lymph have to be seen between the sixth and eighth days.

During a recent visit to England I spent some time looking into the status of glycerinated lymph, and through the courtesy of Drs. Macfadyean, Blaxall and Green of the Institute of Preventive Medicine, I was convinced that the material supplied by that institute differed from ordinary fresh or dried lymph only in its greater assurance of non-septic results.

2. Lancet, 1898, May 7, 14, 21.

The vesicle on the eighth day is typical in shape, from one-eighth to three-eighths of an inch in diameter, and is usually umbilicated. The areola, which is claimed by the American maker to be due wholly to contamination with non-specific and undesirable germs, is not always present, but is usually so, and often of considerable extent. The operators at the laboratory and at the Government Animal Vaccinating Station in Lambs Conduit street have an enormous experience with all kinds of lymph, and their clear and objective record indicates perfectly normal, but unusually pure material. Such results as have been described above they held to be abortive, and, while admitting they might give protection for a few days, or even for a month, insisted they were not to be depended upon.

Besides the marked differences in the human lesion, I noticed some other differences in the action of the lymph. The vesicles on the heifers were much larger than those I saw on the animals in this country, being like those on the calves formerly used for direct vaccination in certain European cities. The British laboratory men all assert that the lesions on heifers are smaller in summer than in winter, and as it was in winter that I saw the imperfect vesicles in this country, the difference is still more suggestive.

The quantity of lymph in the tube is larger in the English product than in any I have seen in this country. The tubes are guaranteed for one week only, and, while this seems too short for our great distances, the three months' limit here is certainly unnecessarily long.

In conclusion I would submit the following:

1. Glycerinated lymph properly raised and prepared offers less danger of septic infection than any other kind of vaccine virus, and, notwithstanding the disadvantage of slow drying, it is to be preferred to dry points as made at present.

2. The peculiar features of the vaccine vesicle as known since the days of Jenner are due to the specific virus; any marked variation from them must be looked upon as evidence of imperfect protection.

3. Virus that produces an imperfect lesion should not be used, because, though it may induce immunity for a short time, may even prevent the taking of an active lymph inserted soon after it, it is likely to obscure the real condition of the subject and set up an unfounded feeling of security.

4. A knowledge of the natural history of normal vaccinia is very desirable for the physician.

5. The vaccination histories of all cases of smallpox, varioloid and chickenpox should be ascertained and recorded as fully as possible.

6. Makers of vaccine virus should give clear and explicit statements as to the quality of their products. The mere assertion of freedom from pyogenic germs covers only part of the case. Evidences of specific activity, as from use in the human being, should be given. For the makers, the results of variolous inoculations in vaccinated monkeys, as suggested by Copeman, would seem very useful and almost essential to the maintenance of a proper standard.

7. A government station for the making and testing of vaccine virus is highly desirable. This need not interfere with private enterprises, but, properly conducted, would be of great value to the latter.

8. Public vaccinators should be trained for their work, and facilities should be given for others to study the methods and clinical features of vaccination.

SATURDAY, DECEMBER 21, 1901.

THE VACCINATION QUESTION.

The antivaccination agitation, which has shown surprising strength in England during the past decade or two and more recently in Switzerland and elsewhere, is evidently rapidly gaining followers in this country. Recent events are liable to give impetus to the movement, which thus far has had but little influence here. The fatal cases of tetanus following vaccination in Camden, N. J., and in one or two other cities, will certainly have a tendency to help in this opposition. It is very probable that these deaths were not the result of vaccination at all, at least not from the virus, and it is extremely doubtful if the vaccination wound had anything to do with the fatal disease which developed incidentally afterward. But the antivaccinationists will make all the use possible of these fatalities to help along their propaganda. Like all such enthusiasts, they are not at all particular as to the absolute facts in such cases, if they can use them to advance what they believe to be a righteous cause.

There is another thing that is liable to make this antivaccination cause more popular, and that is the extremely mild type of smallpox that has prevailed the last year or two. The frightful horror of the disease in its more malignant form had a powerful influence in making people willing to submit to an operation that might otherwise be resisted for one reason or another. It was not only the fatal results that were dreaded, but the facial disfigurement that followed the victim through life. A theoretical objection based on possible results quickly vanished when death or lifelong disfigurement threatened. But with the recent and present epidemic it is different. Deaths are so rare that the disease causes practically no anxiety in this regard, and the resulting disfigurement from the pitting is so slight that few dread smallpox on this account. Under the circumstances, there need be no surprise if the antivaccinationists increase in number and influence in this country as they have in England, and succeed in influencing legislation here as they have there.

But there is another phase of the vaccination question to be considered, and one in which we as physicians are especially interested, because of its great importance, as it relates to preventive medicine. We refer to the use of unreliable virus, to which Professor Dock calls attention in our columns this week.[1] There have been hints from various parts of the country of the unreliability of much of the vaccine supplied, not by one firm only, but by several. The question of the reliability of the virus is a most serious and important one, and the time has come when the matter should be thoroughly investigated. At the present time each individual physician is compelled to depend on the virus supplied to him by the various firms that sell it, both as to its purity and efficiency.

Either there is some ground for the charge that certain houses are placing impure or unreliable virus on the market, or there is not. If there is, then steps should be taken to place the blame where it belongs. If there is no ground for complaint, then this should be ascertained for the sake of the accused firms, as well as for the satisfaction of those who have to bear the sole responsibility of using vaccine virus. Attention to the facts brought to notice, for example, by the Chicago Health Department last January would possibly do away with some of the evils complained of, which may be only the result of the use of unripe virus or that which has passed its time-limit of efficiency. It was then pointed out that glycerinated vaccine could be relied upon to be sterile only after a certain period, placed at sixty days, and that its efficiency was certain only for some forty days longer. Its specific property can not be indefinitely preserved. This is a long known fact, but one possibly too often neglected by the makers and users of vaccine virus. What is needed is to have its limitations authoritatively stated to the profession, so that it may govern its conduct accordingly.

But where are we to look for this authority, and who or what body shall conduct the investigation? A few of the city boards of health have investigated for themselves and to their own satisfaction, we are told, but there has been no publication of their findings, except as above mentioned. Further, one or two investigations will not be satisfactory. Smallpox, to a greater or less extent, is prevailing all over the country and the inquiry must, therefore, be national in its scope. The National Government ought to assume this responsibility, but there is no branch of the government as now constituted that is prepared for such a work, or that has the authority to undertake it. Evidently, if it is done, it must be by the profession itself through its national body, the American Medical Association. We believe that the Association as now constituted can conduct such an inquiry through a well-organized committee that shall be national in its scope, fearless in exposing fraud, reliable in its findings, and satisfactory in results accomplished. It is certainly worthy of being considered. If the present mild type of smallpox should gradually, or suddenly, develop into a more malignant form, and it should be discovered too late that many of those supposed to have been vaccinated do not prove to be immune, then not only may we expect frightful results, but vaccination as a preventive measure would suffer.

1. See p. 1677.

We have more than once urged our readers to be prepared for a more serious form of smallpox to develop from the present mild one, and we still believe that this possibility should be recognized. Vaccination, if properly done with reliable material, is a preventive of this disease, and there is no fact in preventive medicine more demonstrable. Accepting these two propositions as true the duty of the profession is plain.

TYPHOID FEVER IN CHILDREN.

Twenty years ago it was generally agreed that typhoid fever rarely developed in children under the age of five years. The reason for this supposed comparative immunity was often discussed and it was generally accepted that even the fact of the simpler diet of such children causing little irritation and consequently providing fewer opportunities for the invasion of the disease, was not of itself sufficient to account for its comparative rarity. The assumption of some special protective factor as specific immunity seemed necessary to explain the infrequency of typhoid fever in young children. From more careful observation and more scientifically exact diagnosis, it has developed that this supposed immunity is only imaginary. Children of any age, except for the protection afforded by their fewer opportunities of infection, are just as liable to contract typhoid as older people.

Eichhorst[1] says that the transmission of typhoid bacilli from the mother to the child *in utero* has been frequently observed. Typhoid bacilli have been demonstrated in the enlarged spleens of dead-born children whose mothers had been sufferers from typhoid. In these cases the ordinary characteristic lesions of typhoid fever—ulcerations of the intestines, infiltration of the follicles and enlargement of the mesenteric glands—were also present. Typhoid bacilli have been found in the placental blood, and in recent years Chantemesse and Widal have experimentally demonstrated the possibility of typhoid bacilli finding their way through the animal placenta. Hence, even the very earliest age is not protected by any special immunization from the invasion of typhoid bacilli.

The false impression that the disease is rare in children is due to the fact that the symptoms in children are apt to be atypical and that they may not point to any involvement of the abdominal organs. In a large series of cases of typhoid fever recently reported[2] to the Section on Pediatrics of the New York Academy of Medicine, some of the patients presented none of the classical symptoms of the disease on admission to the hospital. Typhoid fever was rather common in New York during the latter part of August and September and it was made a routine practice to make a Widal test in every case presenting continued febrile symptoms. In a number of cases apparently of ordinary summer complaint, in some cases of lobular pneumonia and meningitis, the Widal test was positive and subsequent clinical observation seemed to justify the diagnosis of extra-intestinal typhoid fever.

In some of these very atypical cases investigation showed that the little patients had been exposed to possible infection with typhoid bacilli, or cases of typical typhoid fever developed afterwards in the family or neighborhood. The possibility of such anomalous and unsuspected cases proving a center of infection for a family or institution can, as pointed out by Dr. Koplik,[3] scarcely be exaggerated. The lesson of the cases seems to be that, in febrile affections in children, typhoid fever must always be excluded, unless the symptoms evidently point to some definitely recognizable specific type of disease. Children even at an early age are quite as susceptible as at any time in life to typhoid infection. If exposed their low resistive vitality makes them especially liable to become the victims of the disease and they may readily become foci for the dissemination of typhoid bacilli because of the unsuspected nature of their atypical affections.

THE PATHOGENESIS OF EXOPHTHALMIC GOITER.

Views concerning the pathogenesis of exophthalmic goiter have undergone many changes. By some the disorder was considered a dyscrasia, due to impoverishment and deterioration of the blood. By others the symptoms were ascribed to alterations in the heart and the vascular system. Later, derangement of the nervous system—either the cervical sympathetic or the medulla—was held responsible for the condition, while recently the manifestations have been attributed to excessive functional activity of the thyroid gland, and, last of all, disease of certain glandular bodies designated parathyroid, two on each side of the thyroid gland, are accredited with etiologic significance. It appears that some functional relation exists between the thyroid gland and the parathyroid bodies. A number of experimental observations go to show that the removal of the latter gives rise to secretory and histologic changes in the former—consisting in disappearance of the colloid substance and hypertrophy of the gland—and that these can be prevented by administration of parathyroid substance. From existing evidence it is believed that removal of the thyroid gland causes trophic disturbances similar to those of myxedema in man, while removal of the parathyroid bodies causes convulsive disorders and death. The symptoms of exophthalmic goiter are essentially of nervous origin, and it must be inferred that they are brought about by the action of certain substances that find their way into the circulation as a result of the deranged function of the thyroid gland.

At the last meeting of the British Medical Association Mr. Walter Edmunds[1] presented a preliminary communication detailing experiments on dogs, in the course

3. In Discussion, Section on Pediatrics, N. Y. Acad. of Med., Nov. 14, 1901.
1. Brit. Med. Jour., Sept. 21, 1901, p. 773

of which it was demonstrated that removal of the thyroid gland and the parathyroid bodies was attended with changes in the spinal cord and the medulla. These consisted in loss of definition of the Nissl bodies, the substance sometimes appearing as fine dust, the chromophilous elements sometimes seeming fused together and having in fact undergone chromatolysis. In some of the cells the chromophilous substance was absent, only the network within the cells being visible. In some of the cells there was considerable swelling of the nucleus, and of some of the cells the processes were wanting. In fact, cells were found in every stage of degeneration. These changes are similar to those that have been described as a result of some forms of acute poisoning, and it is fair to consider athyroidea as a variety of acute poisoning, affecting the central nervous system. As the symptoms of exophthalmic goiter more nearly resemble those following excision of the parathyroid bodies than does myxedema, which is due to disease of the thyroid gland, it must be concluded that the former disease is due to aparathyroidea, the presence of parathyroid secretion being necessary for the extraction from the blood and the deposition in the cells of the Nissl bodies, which are supposed to constitute nutriment for the cells.

PARTISAN POLITICS AND OUR INSANE ASYLUMS.

The scientific treatment of insanity and care of the insane in public institutions is a matter in which some portions of our country do not shine with special brilliancy. Nor are they likely to, as long as the ideal qualifications for a physician in charge are such as indicated below. The passage is a verbatim quotation, omitting names, etc., for reasons that can be easily appreciated.

> The selection of Dr. ———, of———, as the superintendent of the hospital ———, at ———, by Gov. ——— is to be commended by every citizen of ———, and especially by every Republican in the central portion of the state. Dr. ——— deserves the appointment and is qualified to fill the position. His services to the Republican organization cover many years. As the head of the Republican county organization in 1896 he gave the party splendid service, service given at the expense of his professional practice and by personal sacrifice. Under his leadership the Republicans of ——— approached nearer a state of practical harmony than it has been [sic] before in many years, and, it may be added, has ever been since. It was hoped and was promised later that Dr. ———'s services in this connection would be rewarded by the appointment he has now received, and the promise of Gov. ——— was given and announcement made. But realization of hopes and the salary failed to come.

We have already held that it is perfectly proper for a physician to take an intelligent and active interest in politics. In fact, we hold that if more of them did even at some sacrifice on their part, it would be better for the country as well as for the profession. But we do not advocate this for the sake of spoils; least of all when it implies the bringing of hospitals for the insane into the political fighting lines. If any public or charitable institutions should be neutral politically those for the care of the insane should be, and there is no possible excuse for them being otherwise, except the desires of political corruptionists in all political parties. It is a degradation to humanitarian instincts and a misuse of public funds wrung from the taxpayer on the pretence of their being devoted to the welfare of the helpless insane; it is a steal as much as any of the Tammany performances that have led to the recent New York revolt against its misrule. The trouble is we have tolerated it so long that we do not realize this fact. Political management of such institutions means mismanagement, as is shown by abundant evidences. There are asylums where public scandals arise as frequently as revolutions in Venezuela, and others that escape only because they are less under the public eye. It is true that some political appointees do well, are good administrators, if not good psychiatrists, but in their case something besides their political services was considered in their appointment. Occasionally, even a man of eminence in the profession may be thus appointed; the pity is that his fitness can not save him if the charge of offensive partisanship is raised by an incoming administration. Each political appointment perpetuates the evil, and so long as partisanship is considered a qualification it will continue. There should be a medical public opinion on this matter to help bring about better things which will be more to our credit as a profession than are the conditions existing. Physicians should not enter politics merely or mainly for the bones that may be cast to them by politicians—who regard public charities as private plums—but for the good they can do; their participation in public affairs should be of a kind that elevates, not degrades, the profession. There is abundant opportunity for this and it will pay best in the end.

THE ACTION OF TOXIC SERUMS ON PERIPHERAL NERVES.

Peripheral neuritis is often associated with autotoxic conditions, as is the case in certain infectious diseases like tuberculosis and diphtheria. As the anatomic changes in the affected nerves are similar in many of these cases it lies near at hand to look for a similar pathogenesis. Reasoning along these lines suggested to Dopter[1] to arrange for a series of experiments in which he brought the blood serums from human patients with various diseases directly into contact with the nerve trunks of guinea-pigs. In each case a control experiment was made in the same way with normal serum; in no case did any changes develop in the nerves in the control animals. In the majority of the other experiments there developed the symptoms and the lesions characteristic of peripheral neuritis. The serums of uremic, diabetic, cancerous and other patients, all caused degenerations similar to those produced by Dopter and Lafforgue with bacterial toxins applied directly to the nerves in another analogous series of experiments.[2] The intensity of the degenerations, more or less purely Wallerian in type, varied with the serum

1. Arch. de Méd. Exp. et d'Anat. Path., 1901, xiii, 779-790.
2. Loc. cit., 507.

employed, and in the case of the same serum its action did not have the same intensity in all animals. From the results of his experiments Dopter is inclined to regard the peripheral neuritis of toxic states as due to the direct action of the toxic products in the circulating blood upon the elementary fibers of the nerve trunks.

LONGEVITY IN IRELAND.

It is said, on the authority of the registrar-general for Ireland, that 20 per cent. of the population of that island die of old age, and it would appear that that is not very rapidly fatal as there were living there in 1900, 212 men and women over 100 years of age. If these are facts it may be a question whether in some points of view they are so much a matter for unmixed satisfaction as might at first appear. Considering life as a blessing in itself, and most normal individuals hold this opinion practically if not theoretically, the showing is eminently satisfactory. Nevertheless a high percentage of deaths from old age must necessarily imply a much larger proportion than one-fifth living past the period of active usefulness, and this by so much lessens proportionately the active and productive part of the population. Taking account of the emigration, of the drafts on the young man for military service, which has always been favored by the Irish, and of this special vitality and longevity, it would seem that Ireland must be a country of old people par excellence. The longevity also indicates that life must be taken easy over there; nothing shortens it more than worry. Possibly the strenuous living Hibernians have come to this country where they can work off their energies in generally getting on in the world. Another corroborative fact as to the general well-being of the Irish and the comparatively small proportion of young and productive individuals is the reduced birth rate, which is a usual accompaniment of thrift and prosperity, and which is said to be lower than in any other portion of the British Isles. Taking all the data together and estimating their significance, it would seem that we ought not to consider Ireland a bad country to live in, but must infer that possibly the green island averages fairly well among the other parts of the earth.

THE OHIO DECISION ON OSTEOPATHY.

It would appear from the newspaper comments that the alleged great victory of osteopathy in the recent Ohio decision,[1] which holds that its practice is comprehended in the statutory definition of the practice of medicine, may prove a boomerang after all. The decision pronounces against discrimination, and therefore none in their special favor can be allowed. As they are not authorized to administer drugs or perform surgical operations, they may be exempted from examination in those departments, but there would be no good excuse for their being relieved from the examination required in other branches. The fact that the Ohio medical practice statute does not specify the number of years that a candidate for license to practice medicine must have attended lectures, leaving that to the board, while this is specified for the osteopaths, is considered as discrimination by the court and therefore void. This does not exempt the osteopaths from examination; it can not create another discrimination in their favor. The law is pruned down, therefore, as regards this point by the decision, and that the individual involved in the case goes free is a matter of no importance. The Ohio State Board is said to be well satisfied with the court's findings; it makes the osteopaths subject to the same rules as all other practitioners, except as regards their special exclusive dogma and practice. The board can compel them to show that they have a satisfactory knowledge of anatomy, physiology, pathology, chemistry "and such other subjects as the board may require." On the whole, the decision seems to have disposed of only a very unimportant feature of the law that was probably introduced only as a blind or for the benefit of the so-called osteopathic colleges which are springing up in various parts, and to have left its essentials untouched. It, moreover, by implication rules out discrimination in favor of any irregular practitioners and that is just what will not suit them. The rejoicing of the osteopaths may be found by them to be a little premature and there will probably be wailing and gnashing of teeth again very soon. It does not appear how they can help themselves, however, when the State Board summons them to undergo examination unless the legal mind finds some other flaw in the law in their favor.

STRONGYLOIDES INTESTINALIS IN THE UNITED STATES.

In connection with ankylostomiasis attention was called[1] to the importance of careful examination of the feces in cases of anemia and intestinal disturbances. The injunction to examine the feces for these parasites should be extended to other cases as well; for it appears that when this is done instances of intestinal infection with animal parasites are sure to be discovered sooner or later of which the profession of this country now know little or nothing, because they are not supposed to ever occur here. This is illustrated by the reports of Strong[2] and Thayer[3] of cases of diarrhea associated with the presence of strongyloides intestinalis in the Johns Hopkins Hospital. Both of these writers give careful reviews of the literature. In the first case, observed by Strong, the parasite was discovered in a patient with amebic dysentery and abscess of the liver. In Manila Strong had the opportunity of observing four additional cases. Thayer adds two more from Baltimore. As three cases were recognized in three years in one hospital, all of which probably originated in Maryland and Virginia, Thayer suggests that this parasite may be more frequent than has been supposed. There is some doubt as to the pathologic importance of strongyloides intestinalis. Manson, for instance, states that later investigations since its discovery in Cochin China, by Normand in 1876, while clearing up its interesting natural history, have robbed it of any claim to pathologic import. Strong holds that the parasite while not particularly dangerous is not harmless, causing an intermittent diarrhea and intestinal catarrh. But the discovery of strongyloides intestinalis in this country em-

1. Journal, Nov. 30, 1901, p. 1466.
2. Johns Hopkins Hospital Reports, 1901, x, 91-132.
3. Jour. Exp. Med., 1901, vi, 75-105.

phasizes again the possible occurrence to a greater extent than suspected of ankylostomum duodenale (uncinaria duodenalis) because the geographic distribution of the two forms seems to be about co-extensive. In searching the feces for the ova of the ankylostomum, the observer sometimes is astonished "by seeing a small, snake-like animal suddenly rush across the field of the microscope," and on closer examination this animal is found to be the strongyloides. Enough has been said to show the desirability of careful examination of the feces in both hospital and private practice in order to enable the physician to fully control the situation.

Medical News.

CALIFORNIA.

Crusade Against Illegal Practitioners.—On December 6 the State Board of Medical Examiners swore out warrants against 18 illegal practitioners.

Personal.—Dr. Frank D. Walsh, for four years in charge of the hospital of the Hobart Lumber Company, has located in Santa Rosa.——Dr. William C. Hassler has been appointed chief sanitary inspector of San Francisco, to succeed Dr. William P. Chalmers.

Reports of Communicable Diseases.—The city council of Oakland has passed amendments to its ordinance requiring reports of certain diseases, as follows: "Every physician in the City of Oakland shall immediately report to the Health Office, in writing, every patient he shall have sick of typhus or ship fever, yellow fever, Asiatic cholera, smallpox, bubonic plague, diphtheria, scarlet fever or scarlatina, chicken-pox, typhoid fever, malarial fever, or pulmonary tuberculosis accompanied by expectoration; and report to the Health Office every death from any of the said diseases immediately after it shall have occurred. Every householder in the City of Oakland shall immediately report in writing to the Health Office the name of every inmate of his or her house, whom he or she shall have reason to believe sick of typhus or ship fever, yellow fever, Asiatic cholera, smallpox, bubonic plague, diphtheria, scarlet fever or scarlatina, chicken-pox, typhoid fever, malarial fever, or pulmonary tuberculosis accompanied by expectoration, and report every death occurring at his or her house from any of the said diseases."

COLORADO.

Dr. William W. Kenney, formerly house surgeon at St. Francis Hospital, Colorado Springs, has entered the Medical Corps of the Army and has been ordered to Fort McDowell, Cal.

Morbidity.—During November, 130 cases of diphtheria, 315 of scarlet fever and 130 of smallpox were reported to the State Board of Health. Compared with October, November shows an increase of 12 cases of diphtheria, 136 cases of scarlet fever and 76 cases of smallpox. The increase is due to the failure at different places to recognize the first case, and the resulting failure to adopt proper measures.

New Regulations.—The State Board of Health has directed all health officers to notify all physicians practicing in their jurisdiction that on and after Jan. 1, 1902, every case of typhoid fever must be reported; and that on and after Jan. 1, 1902, no dead body can be lawfully disposed of without first securing a burial permit. Blanks for both these purposes will be sent to health officers before January.

FLORIDA.

Personal.—Dr. Theodore Turnbull, Monticello, has moved to Jacksonville.——Dr. Louis S. Oppenheimer, Tampa, who has been seriously ill for several weeks, is now convalescent.

Hospital Burned.—The railway hospital of the Flagler system, at St. Augustine, was destroyed by fire, November 27, entailing a loss of $10,000, covered by insurance. There were twenty-four inmates in the various wards, but they were removed without loss of life.

Health of Florida.—The twelfth annual report of the State Board of Health shows that during 1900 there were 9610 births and 5949 deaths. The population of the State is 528,442, which gives a birth rate of 17.99 and a death rate of 11.24 per 1000. The death rate the previous year was 11.67, while the birth rate was 15.50; hence the figures for 1900 are encouraging as showing an advance in the birth rate and a slight decrease in the number of deaths. The six principal causes of death were: Consumption, 493; malarial fever, 330; pneumonia, 316; nephritis, 143; influenza, 133; and paralysis, 111. Out of the 5949 decedents 176 were from old age, being beyond eighty years; 143 from gunshot wounds, and 203 from other violent causes of death, such as drowning, burns, lightning, etc.

ILLINOIS.

St. Clair County Smallpox Hospital, East St. Louis, was formally opened November 21.

Hospital Enlarged.—The work of enlarging St. Anthony's hospital, Rock Island, is already under way. The addition will cost about $30,000.

Smallpox.—Smallpox is prevalent at Posey, where there are four well-developed cases, and at Mount Pulaski, where the existence of 14 cases has caused the public schools to be closed.

Hospital at Rock Island Arsenal.—One of the items of the estimates submitted to Congress by the Secretary of the Treasury is that of $135,000 for a new hospital building and for moving and reconstructing a storehouse at Rock Island Arsenal.

The Gordons Are Doctors.—The family tree of Dr. James Gordon, who died at Greenville, in 1895, shows that 13 of his descendants are physicians; that 7 are studying medicine, that 5 are destined to be physicians, and that two doctors have married into the family.

Personal.—Dr. William A. Gray, Milledgeville, has moved to Freeport.——Dr. Bert Caldwell, Effingham, has located in East St. Louis.——Dr. Arista D. Lloyd, Meyer, has succeeded to the practice of Dr. Jesse H. McIntosh, De Witt. The latter has moved to Hope.——Dr. Henry Taphorn, assistant county physician of St. Clair County, has resigned.

Decision Regarding Smallpox.—In the case of Granite City against the County of Madison, growing out of an epidemic of smallpox, the expenses of which aggregated $12,000, and in which the county tendered $3800 in gold as its share of the expense, and the Granite City council brought suit to make the county pay all the expenses, the circuit judge held that the county was liable for physicians' bills, necessary food, shelter and nursing. All items incidental to quarantine, such as guards, coal bills, boarding, pesthouse, supplies, etc., were charged to the city in the decision.

Chicago.

Dr. Frank Billings will deliver the Shattuck Lecture at Boston next June. His subject will be on "Changes in the Spinal Cord in Pernicious Anemia."

New Buildings Needed at Dunning.—The president of the County Board estimates that for $500,000 he could replace the present old and inadequate buildings at Dunning by new ones, built in modern style that would be a credit to the county.

Smallpox.—The almost marvelous exemption of the city from smallpox still continues. This is in striking contrast to the conditions in nearly all of the large cities of the country, if not of the world, outside of Germany, in which smallpox has become practically extinct through its efficient vaccination and revaccination system.

Weekly Bulletin.—Public health conditions as indicated by the mortality figures of last week, remain substantially unchanged. There were 18 fewer deaths reported than during the previous week, and the annual death rate was 13.39 per thousand, as against 13.93 for week ended December 7. The death rate among those under 5 years of age is gratifyingly low, and the previous excess among those over 60 was materially decreased last week. Pneumonia headed the list with 77 deaths; consumption was next with 48 deaths.

Influenza and Pneumonia.—There is no abatement, but the contrary, in the spread of influenza, the perniciously active first lieutenant of pneumonia, which, as shown in the March Monthly Bulletin, has, during the last dozen years, displaced consumption as the "captain of the men of death," to apply the phrase of John Bunyan. Both the pneumonia and the influenza germs continue to be found in increasing numbers in the laboratory examinations, and the closing forty-eight hours of the week ending December 7, with the sudden and violent change in temperature, afford the conditions best calculated to

develop these germs into activity in the systems of those in whom they had already lodged.

INDIANA.

Typhoid fever exists in Mount Vernon. The health officer states that 25 cases have been reported to him, mostly of school children.

Smallpox is reported as follows: Francisco, 3 cases; Oakland City, 1 case; Mackey, 1 case; Lincoln City, about 75 cases; Anderson, 1 case; Sidney, 26 cases; Pierceton, 3 cases; Packerton, 5 cases; North Madison, 27 cases; Tennyson, 8 cases; Gentryville, several cases, and Tell City, 5 cases.

Action of State Medical Board.—At a special meeting of the board, December 10, the license of Harry S. Kiskadden, Huntington, was revoked, as he was shown to be a non-resident of the state. The board also refused to recognize the Curtis Physio-Medical Institute, Marion. Two cases were continued. The board will hold an examination for license to practice, January 14. About fifty have already applied.

KANSAS.

Report System.—The Topeka Board of Health use the postal card system for reports.

Dr. Charles Hammond, Topeka, has been arrested for failing to report contagious diseases promptly.

Osteopaths to Be Examined.—It has been decided that the State Board of Registration has a right to examine osteopaths.

Smallpox in the State.—Smallpox is not as prevalent now as at this time last year. The following is the detailed statement of all cases reported during November: Arkansas City, 3; Barton County, 9; Chatauqua County, 4; Douglas County, 14; Fort Scott, 25, with 1 death; Girard, 12; Marysville, 6; Meade, 1; Ness County, 7; Phillips County, 3; Shawnee County, 3; Stafford, 19; Topeka, 8; Wellington, 1; Wichita, 6 cases, with 1 death, and Washington County, 16 cases. Total number of cases, 137, with 2 deaths.

MARYLAND.

Naval Academy Changes.—Passed Assistant Surgeon W. H. Garton has been detached from the Naval Academy at Annapolis and ordered to the New York Navy Yard. Passed Assistant Surgeon J. B. Dennis has been ordered to the Naval Academy.

War on Tuberculosis.—The State Board of Health is actively prosecuting its intention of making war on tuberculosis. The secretary has been directed to have an interview with the governor hoping that the legislature will authorize him to appoint a commission to study the means of dealing with the disease most effectually. A hope is even held out that the state may begin this winter the treatment of incipient cases of consumption in public sanatoria.

Abolition of State Aid to Medical Schools.—It is announced that the Board of State Aid and Charities will recommend to the legislature the abolition of all free scholarships and the withdrawal of all appropriations to medical schools. It is claimed that some of the institutions have been receiving aid for 60 years and that the state appropriation for one scholarship to each county and one to each legislative district in Baltimore is simply a raid on the treasury without due compensation.

Special Tax for Insane.—Dr. J. Clement Clarke, of Springfield Asylum for the Insane, proposes the levying of a special tax in this state for the support of the insane. This would involve an increase in the tax-rate of about 3 cents. The present system provides that each county and Baltimore shall pay $150 per year each for insane patients. Dr. Clarke proposes to collect all the insane from the almshouses and jails at Springfield, where there is plenty of land for building purposes. At present there are 405 patients at Springfield. Both asylums are crowded.

Baltimore.

Dr. Daniel C. Gilman has been made president emeritus of the Johns Hopkins University.

Mayor's Veto Sustained.—In the first branch of the city council the mayor's veto on the Municipal Hospital ordinance was sustained. It is probable that the matter will be taken to the legislature.

Baltimore Mortality.—For the week ended December 7 there were 180 deaths, more than half being colored. Typhoid fever caused 5; diphtheria, 1; consumption, 26; cancer, 7; heart disease, 12; pneumonia, 22, and Bright's disease, 13.

Deaths in Baltimore for the week ended December 13, were 189. Pneumonia caused 25, consumption 22, cancer, heart disease and inanition each 11, Bright's disease 10, accidents 9, paralysis 6, diphtheria and suicide each 3, typhoid fever and homicide each 1.

Veto of Ordinance Against Infections Hospital.—The mayor of Baltimore has vetoed the ordinance removing the Infections Hospital Commission and providing that the hospital shall not be erected on the ground purchased a short time ago by the commission for the purpose. All the schools of medicine joined in urging the great need of such a hospital and in expressing the opinion that there is no danger of infection. The mayor points out the injustice done to leading physicians of the city composing the board, who have given their time and services in selecting a suitable site. The board is bound by contract for $20,000 for the above site.

MICHIGAN.

Illegal Practitioner Convicted.—Robert A. Knight, Center Line, pleaded guilty, December 6, of practicing medicine without having registered, was fined $25 and agreed to leave the county.

Michigan Doctors.—Michigan has 4350 physicians who have received certificates under the law of 1899. The population of the state being 2,188,650, the ratio of physicians to laity is as 1 to 503.

Smallpox.—Manistee now stops all trains outside the city limits and has passengers examined as smallpox suspects.——In Breen Township 3 cases have developed, in one of the Ford River Lumber Company's camps.——In Reed City, 5 cases are reported.——At Muskegon 12 cases have been reported and the charge is made that many light cases are being treated privately.

Mortality in Michigan During November.—There were 2454 deaths returned to the secretary of state for the month of November, corresponding to an annual death rate of 12.5 per 1000 population. This number is 94 less than the number returned for the preceding month and 7 less than the number of deaths recorded for November, 1900. Of the total number of deaths returned to the department, 346 were infants under one year of age, 177 were children aged one to four years, both inclusive, and 659 were deaths of persons aged sixty-five years and over. Important causes of deaths were as follows: Pneumonia, 206; pulmonary tuberculosis, 137; other forms of tuberculosis, 29; typhoid fever, 79; diphtheria and croup, 59; scarlet fever, 27; measles, 6; whooping cough, 8; diarrheal diseases of children under two years of age, 42; influenza, 11; cancer, 127; accidents and violence (exclusive of deaths at Wabash wreck), 188. Two deaths from smallpox and two from anthrax are also reported.

MISSOURI.

Dr. Jackson's Estate.—The estate of the late Dr. J. P. Jackson, Kansas City, who died intestate, is valued at $10,000, and the president of the First National Bank has been appointed administrator.

The Alumni of the Medical Department of Washington University held, on December 10, a symposium on tuberculosis, and special emphasis was made upon the necessity for early diagnosis and limitation of the disease by enforcement of sanitary laws.

City Bacteriologist and Pathologist for St. Louis.—As one of the results of the city's recent antitoxin trouble, a bill creating the office of city bacteriologist and pathologist will soon be introduced into the municipal assembly. The bill will be drawn by the medical members of that body.

Smallpox.—The 12 patients in quarantine at the St. Joseph pest-house, which is a dilapidated shack on the river front with tents as annexes, complain of accommodations and food, and a subscription for their relief has been started by the citizens.——Independence has 16 cases of smallpox.——In Kansas City 3 cases were discovered, December 9, which were said to have been under the care of a prominent physician, who had not reported them.——At Enoch schools have been suspended on account of 3 cases of smallpox.——At Chitwood 15 cases have been reported.

Fumigation Plus Cleansing.—The subject of tuberculosis is receiving a large share of attention in St. Louis. The original bill for registration and fumigation as presented by the Health Department did not pass the Council, because it was deemed oppressive and futile. A new bill has been agreed upon by members of the board of health and representatives of the

St. Louis Medical Society, and will shortly be offered. One of the provisions is that when requested by the attending physician, the Health Department shall cause the apartment occupied by the tuberculous patient to be thoroughly cleaned and not merely fumigated.

State Sanatorium for Tuberculosis.—At a recent meeting of the City Hospital Alumni, Dr. Homan offered the following resolutions, which were adopted:

WHEREAS, The provisions by state government of sanatoriums for the reception and care of tuberculous persons has become an acknowledged necessity for the better protection of the public against tuberculosis in its various forms; and,

WHEREAS, Several states already possess such sanatoriums, while Missouri, although the fifth state in the Union in order of population, has taken no steps toward providing for the establishment of such an institution; therefore, be it,

Resolved, That the Society of the City Hospital Alumni recognize the urgent necessity for an adequate institution designed for the exclusive care and treatment, both hygienic and medical, of tuberculous persons in the State of Missouri, the said institution to be erected and maintained by the state government; and that this Society shall at once, by correspondence and otherwise, seek to enlist the active co-operation of other medical societies and bodies, and of the public press throughout Missouri to the end that a sanatorium, commensurate with the importance of the object sought, be authorized by legislative action, the same to be erected in some suitable location in the mountainous part of the state.

MONTANA.

St. John's Hospital, Helena, will be ready for occupancy, January 1.

Contract Physicians.—The County Commissioners have been awarding contracts for medical services for the county poor to the lowest or to sufficiently low bidders. In Yellowstone County $300 is paid; in Choteau County, $1260; in Custer County, $650; Meagher County, $300, and Beaver Head County, $600.

State Board Sustained.—The action of the State Board of Medical Examiners in refusing to grant William F. Clarkson, Butte, a license to practice medicine in the state was sustained. The case came before the District court on Clarkson's appeal from the action of the State Medical Board in refusing to issue him a license on the ground that his examination was entirely unsatisfactory and the board did not consider him a safe person to be allowed to practice.

NEBRASKA.

Omaha has 52 cases of smallpox under quarantine.

The State Board of Health met at Lincoln, December 6, and issued licenses to five physicians and two osteopaths.

Dr. A. N. Loper, who for the past seven years has been superintendent of the Nebraska Sanitarium, Lincoln, has accepted a similar position in the St. Helena Sanitarium, St. Helena, Cal.

The Smallpox Situation.—The reports to the State Board of Health indicate that the disease is being effectively fought in the various communities where it has broken out. The counties are organizing local boards of health and where they had not already formulated quarantine rules are adopting those recommended by Dr. Towne and the secretary of the state board. The disease is well under control in Long Pine and other places in that section of the state, but the danger is by no means passed. A strict observance of quarantine rules is essential.

NEW JERSEY.

Increase of Cancer.—The State Board of Health's report shows that in the year ended October 31 there were 1001 deaths from cancer, or twice as many as from smallpox, diphtheria, scarlet fever and typhoid fever combined in the state.

Library House-Warming.—The house-warming of the William Pierson Medical Library Association took place in the Stickler Memorial Library building, Orange, December 4. There was a large attendance of prominent physicians from the Oranges, Newark and surrounding towns and cities and other invited guests. Fifty-four members and a large number of applicants attended the meeting. The president, Dr. Thomas W. Harvey, Orange, opened the meeting with an address of welcome, and then introduced Dr. Charles McBurney, New York, who delivered a lecture on "Aseptic Surgery." At the conclusion of the address a collation was served.

Tuberculosis Sanatorium.—The Camden County Medical Society has passed the following resolutions:

WHEREAS, Tuberculosis is a constant factor in the mortality of the state, causing each year more deaths than typhoid fever, scarlet fever, diphtheria, croup, measles, whooping cough and smallpox combined, and amounting to about 11 per cent. of the death-rate, and,

WHEREAS, Tuberculosis is an infectious, contagious disease, communicable through air, food and personal contact; and,

WHEREAS, Science has demonstrated that the disease is preventable, and in a large percentage of incipient cases, curable, and that,

WHEREAS, The plan of segregating tuberculous subjects, the incipient cases in camps or sanatoria and the incurable cases in hospitals, has been tried abroad and in several states and found to offer the best means for the cure and eradication of the malady and the protection of the public health; therefore, be it

Resolved, That this Society recommend to the representatives of Camden County in the Legislature the enactment of a law providing for the establishment of a sanatorium, under State supervision, for the treatment of incipient cases of tuberculosis, which shall afford the best facilities for the personal care of the subject and the cure of the disease;

Resolved, That the authorities of each county be authorized by enactment to establish hospitals for the care and treatment of incurable cases, since the best results can be obtained only from treating the incipient cases apart from the incurable.

NEW YORK.

Onondaga County Hospital.—The hospital at the County house, Syracuse, has been completed, and the patients in the old building transferred to it. It is a model building, and $31,000 has been expended on its construction and equipment.

Medical Course Extended.—The Cornell Faculty of Arts and Sciences met December 11 and decided to extend the course for the A. B. and medical degrees from six to seven years. Hereafter no art student will be allowed to register in the medical course unless in the beginning of the senior year. Two years of the seven will be spent in the New York department and five in Ithaca.

Endorses Vaccination.—The Rochester Pathological Society, at a recent meeting, adopted resolutions declaring that smallpox was more than usually prevalent, publicly affirming its belief in the effectiveness of vaccination as affording protection against smallpox; urging the prompt vaccination of all unvaccinated children, and the revaccination of all persons whose protection has not been tested by revaccination within the last five years.

Consumptives Barred.—The Board of Health of the village of Liberty, fearing that the popularity of that place as a resort for consumptives might interfere with public health, and so with its popularity as a summer resort, has passed an ordinance putting tuberculosis in the same class as smallpox, scarlet fever and diphtheria and imposing heavy fines on any one maintaining a "hospital, pest-house or sanatorium" for consumptives inside the village limits.

The New York County Medical Association and Society.—New York County Medical Association, at its stated meeting on December 16, adopted the following preamble and resolution:

WHEREAS, The following resolution has been received from the Medical Society of the County of New York: *"Resolved*, That the President of the Medical Society of the County of New York appoint a committee of five, of which he shall be chairman, provided a similar committee be named by the New York County Medical Association, to confer with that body with reference to a union of the two organizations; and that this committee be requested to report to the Society at the stated meeting in January, 1902, or sooner, in order that this Society may, if desirable, make a recommendation to the Medical Society of the State of New York at its next annual meeting;" and,

WHEREAS, The subject of union of the medical profession in this state, as expressed in the foregoing resolution as presented by the Medical Society of the County of New York, is wholly a state question: and,

WHEREAS, The published charter and by-laws of the New York State Medical Association do not allow its county associations to act independently on state questions;

Be It Resolved, That we heartily favor a union of the profession in one state medical body, and respectfully suggest that the Medical Society of the County of New York request the Medical Society of the State of New York to appoint a committee to consider this question; and,

Be It Further Resolved, That the New York County Medical Association request the New York State Medical Association to appoint a committee of conference in case the Medical Society of the State of New York shall appoint a similar committee.

Buffalo.

Dr. Arthur W. Hurd, superintendent of the Buffalo State Hospital, has been granted $200 for his examination of Czolgosz.

Dr. G. F. Mills, formerly of the house staff of the Erie County Hospital, has been appointed on the staff of the Manhattan State Hospital, New York City.

State Commissioner in Lunacy.—It is reported that Governor Odell has appointed Hon. Daniel Lockwood as State Commissioner in Lunacy, a position which pays $5000 and $1200 for traveling expenses.

Marine-Hospital for Buffalo.—In his report to Congress, Secretary of the Treasury Gage notes that the Surgeon-General

of the United States Marine-Hospital Service recommends an appropriation for the establishment of a marine-hospital at Buffalo, and approves the recommendation.

Smallpox.—Many stores and factories are still continuing in the compulsory vaccination of their employes. The health authorities made an inspection of all inhabitants on Laepere Street (where most cases are at present) and all those whose vaccination did not take or who had not been vaccinated were compelled to comply. The Street Railway Company has undertaken to fumigate the street cars and all the employes are undergoing vaccination.

New York City.

Dr. William B. Pritchard has been appointed consulting neurologist to the S. R. Smith Hospital, New Brighton, Staten Island.

Dr. Rowland G. Freeman has been elected chairman of the Section on Pediatrics of the Academy of Medicine, and Dr. David Bovaird, Jr., secretary, for the ensuing year.

An epidemic of scarlet fever has broken out in the Hebrew Orphan Asylum, Brooklyn, where 315 boys are housed. Ordinarily 250 of the children attend school in the neighborhood, but this has been stopped and the asylum placed under quarantine.

Dr. James W. Bowden, a physician living at Yonkers, but doing business in New York City as medical examiner for one of the life insurance companies, while engaged in his professional work in this city suddenly lost his identity. He had just made a call upon a private patient, and had insisted upon calling in consultation a surgeon. He left the patient's house saying that he would return with the surgeon in two hours, and when this time had long passed an effort was made to discover his whereabouts. The police were finally notified, and a large force of detectives searched for him, but two nights and two days elapsed from the time of his disappearance before they discovered him. It is reported that when found his mind was almost a complete blank, but that it is expected he will soon recover completely.

Deportation of Consumptives.—The first case to test the constitutionality of the Treasury ruling, that consumptives shall be prevented from landing in this country as immigrants, has just come up. One Thomas Boden, and his family, arrived here on November 9, and relatives from Philadelphia guaranteed that they would not become a public charge. The authorities refused to admit Mr. Boden to the country because the examination made by the Marine-Hospital physicians showed him to be suffering from pulmonary tuberculosis. He was ordered deported, but a lawyer obtained a writ of habeas corpus, and Mr. Boden is now a government patient in the Long Island College Hospital. The act of Congress under which he is detained was intended to exclude idiots, insane, paupers, criminals and "persons suffering from a loathsome or a dangerous contagious disease."

OHIO.

Smallpox at Mingo Junction is said to be under control.

State Board Examination.—The State Medical Board examination was held in Columbus, December 10, 11 and 12. There were 32 applicants.

Massillon State Hospital.—The annual report of the Massillon State Hospital has been filed. The trustees recommend the purchase of 85 acres of land at a price not to exceed $200 per acre, and also ask appropriations for a hospital building, an infirmary and seven cottages. The estimates for 1902 are $321,000 and for 1903, $359,700. The per capita cost, including officers' salaries, was $141.81.

Anti-Tuberculosis Committees.—The president of the Ohio Society for the Prevention of Tuberculosis has announced the following committees: Legislation; auxiliary societies; public institutions; sanatoria; lecture bureau; workshops and factories; publication; animal tuberculosis and sick benefits. He also appointed a special committee to investigate and report on the prevalence of tuberculosis in cities.

PENNSYLVANIA.

Marine-Hospital at Pittsburg.—Congressman Dalzell has introduced a bill in Congress appropriating $100,000 for the purchase of a site and the building of a marine-hospital in Pittsburg.

A physician of Spring City was fined $25 and costs, December 7, for alleged failure to report to the Board of Health a case of smallpox he was treating. He will appeal from the decision of the Burgess.

Want Fees Advanced.—The physicians of Sharpsburg and Etna are making an organized effort to obtain adequate fees. At present the fee-bill is 50 cents for office calls and $1 for visits. These fees should, in their opinion, be doubled.

Smallpox.—An epidemic exists in Schuylkill County; at Auburn there are 25 cases and 6 at Port Clinton, 1 at St. Clair and several at Tamaqua.——Two cases are reported from Rosato, near Bangor.——Near Hoffer, Snyder County, there are six cases.——Plymouth, where the disease has existed for a year, and where there have been 22 deaths, has been quarantined by Wilkesbarre.——Lebanon has 24 cases.

Philadelphia.

Wills Eye Hospital, under control of the Board of City Trusts, is to have a change of management, Superintendent Richard H. Lytle having resigned.

State Medical Board Examinations.—The State Medical Boards of Examiners, regular, eclectic and homeopathic, examined applicants for license to practice medicine this week.

Pathologic Exhibit.—The Philadelphia Pathological Society will hold a special annual exhibition meeting, January 9. Many fine bacteriologic and tissue specimens, both microscopic and gross, will be shown.

New Laboratories.—To help in building medical laboratories for the University of Pennsylvania, Dr. R. V. Mattison recently subscribed $25,000. To make room for the buildings, the Veterinary School is to be moved.

The North Branch of the Philadelphia County Medical Society held a meeting, December 10. The program consisted of a symposium on variola, varicella and vaccinia. Drs. Joseph McFarland, Jay F. Schamberg, William M. Welch and Judson Daland presented different phases of the subject, and the chief medical inspectors, vaccine physicians and other authorities engaged in the discussion.

Contracts Awarded for Blockley.—Dr. John V. Shoemaker, president of the Board of Charities and Correction, announces the award of contracts for Philadelphia Hospital (Blockley) work as follows: A maternity house, to be completed in 125 working days, at $9500; a children's hospital, completion required in 175 days, at $33,275, and a hospital for contagious skin diseases, completion in 175 days, at $33,175.

Vaccination.—The official report of the Camden, N. J., Board of Health, relative to 11 cases of tetanus following vaccination in that city, is gratifying to the profession at large, and should be especially so to the physicians as well as to the laity of Philadelphia at this time of an imperative need for vaccination. The investigation established the fact that all virus used in Camden was free from tetanus, as shown on examination by the state bacteriologist; by tests on rats by Cooper Hospital physicians, and by the fact that in none of the cases did tetanus, which was acute, occur until 3 or 4 weeks after vaccination. In Philadelphia, within the past three months, 700,000 to 800,000 persons have been vaccinated with the same kinds of virus as those used in Camden and not a case of tetanus has occurred. The cases of tetanus are ascribed in the report, to a long period of dry weather, with high winds, and to a lack of proper care on the part of patients to the vaccination wounds.

The Smallpox Situation.—According to the official report more new cases of smallpox developed in the city in the past week than heretofore. In the week ended November 30, the next highest number, 113, occurred; last week 125, as against 72 for the intervening week. Eight deaths occurred the past week. The total number of cases reported since the beginning of the year is 965, deaths 127; cases under treatment at present, 349. To stamp out the disease, under the direction of Dr. W. M. Angney, assistant medical inspector, an extra corps of about 60 physicians has been organized, and they are making a house-to-house canvass. This corps, appointed upon the recommendation of the deans of the medical colleges, is in addition to the 33 permanent regular physicians who vaccinate in their offices only. The extra corps has made, in the week's work, about 11,000 vaccinations. They are paid by the city. In view of some apprehension regarding tetanus, the physicians are directed to use careful technique and to instruct patients in the protection of the wounds. Because of the small capacity of the Municipal Hospital, it is necessary to treat many cases in their homes. Such houses are quarantined and guarded by police or special quarantine officers.

TENNESSEE.

Cornerstone Laid.—The cornerstone of the new laboratory for Meharry Medical College, Nashville, was laid, December 3.

Dr. William D. Haggard, Jr., Nashville, who was operated on for appendicitis last week by Dr. L. S. McMurtry, of Louisville, Ky., is improving satisfactorily.

Doctors Won.—In the suit of M. Cohen against Drs. William B. Rogers and Frank D. Smythe, of Memphis, for $15,000 damages for the loss of an arm, the jury returned a verdict for the defendants, December 10.

Right of Way for Doctors and Ambulances.—An ordinance was passed, December 5, by the Legislative Council of Memphis, and approved by the mayor, which grants "the right of way to all such persons who practice for the cure of the sick and the injured, and all such vehicles which are exclusively used for the transportation of the sick and the injured."

Smallpox.—During November 3 cases were treated in Chattanooga.——There are 4 cases in the Weakley County pesthouse.——Dr. John E. Parks, Somerville, physician of Fayette County, is ill with the disease.——In Johnson's Grove, Crockett County, there are 4 cases and many exposures.——Jackson County has 5 cases; Lauderdale County, 3 cases; Shelby County, 8 cases; and Fayette County, 8 cases.

CANADA.

University Quarantined.—Ottawa University is quarantined owing to two or three cases of smallpox having developed among the student body, which numbers about 600. There have been over 90 cases of smallpox at the capital since the beginning of the outbreak.

Physicians in Lumber Camps.—Dr. Hodgetts, special sanitary inspector to New Ontario, is at the present time in Toronto. He reports that fifty lumber firms and companies have appointed physicians to look after the men in their shanties in the lumbering and mining districts to the north.

Personal.—Dr. G. E. R. McCartney left Toronto on December 7 for New York to assume his duties as house surgeon of the New York City Hospital, a position which he will hold for the next two years.——Dr. James G. Ross, London, Ont., has removed to Chicago to practice.

Appointment.—Prof. J. T. Ronald has been appointed public analyst at Montreal. The work of protecting the public against impure and adulterated foods, drugs, etc., is under the supervision of the Department of Inland Revenue at Ottawa, with a chief analyst in charge. The dominion is divided into districts, and each month officers purchase in the open market samples to be analyzed, and it is thus that offenders under the adulteration act are dealt with.

New Order of Trained Nurses.—For some time there has been considerable opposition on the part of the Roman Catholic church authorities in Montreal to Catholics employing Protestant trained nurses and to obviate this Archbishop Bruchesi has addressed a pastoral letter to the Catholic clergy ordering the establishment of an order of Catholic trained nurses, to be known as the Sisters of Hope, whose duty it shall be to attend the Catholic sick.

Osteopath Convicted.—The case of the Toronto osteopath in whose office a young lady recently died after undergoing treatment for goiter, came up before the police magistrate last week. The Crown had secured the books of the irregular and from these it was ascertained that other than osteopathic diseases were commonly being treated by these "practitioners." The magistrate seemed to have no faith in osteopathy and stated that he would impose a fine of $25 and costs.

Physician Loses Suit.—At a recent sitting of the Division court of an Eastern Ontario town, a physician sued a veterinary surgeon for medical attendance upon his family. The judge gave judgment for the defendant with costs, owing to the fact that the practitioner could not at the time produce a certificate issued by the registrar of the Ontario Medical Council, showing that he was a duly qualified practitioner. This puts a new aspect on the $2 assessment question in the province of Ontario.

University Federation in the Maritime Provinces.—A special meeting of the Governors of King's College, Windsor, N. S., was held on the 12th inst., and the meeting was attended by representatives from New Brunswick, Prince Edward Island and points in Nova Scotia; it had for its object the federation of all the colleges in these three provinces, and the establishment of one great university for all. King's College is the mother university of Canada; and in all the colleges the science departments are sadly neglected. A committee was appointed to open communications with all the colleges concerned.

Dr. Thomas G. Roddick, Dean of McGill.—Dr. T. G. Roddick, M. P., has been chosen by his fellow members of the Faculty of Medicine for the position of Dean rendered vacant through the resignation of Dr. Craik. Dr. Roddick at present holds the Chair of Surgery. He was graduated in 1868 as Holmes gold medallist. He is ex-president of the Montreal Medico-Chirurgical Society, of the Canadian Medical Association and of the British Medical Association. He was elected a Member of the Canadian House of Commons in 1896, since which time he has been prominently identified with the question of inter-provincial registration.

The Toronto Hospitals and Consumptives. — For two years the hospitals of Toronto have refused to admit consumptives to their wards; but the demand of the public press became so strong last week that, coupled with the energetic demands of the Medical Health Officer, they could hold out no longer, and the Toronto General and Grace hospitals offered to take in six patients each who were suffering from pulmonary tuberculosis. It is likely that the Western and St. Michael's will soon follow. The accommodation will extend to such time as the National Sanitarium Association shall require to get their new sanitarium near Toronto completed.

Dr. Lesslie M. Sweetnam, one of Toronto's foremost surgeons, died at Johns Hopkins Hospital on December 11, whither he had gone for treatment for blood-poisoning. Some nine or ten days prior to his journey to Baltimore, he was operating on a man with gangrene of the forearm resulting from a gunshot wound, the patient dying a few days thereafter; and while performing his toilet after the operation the surgeon had the misfortune to prick one of his fingers with the nail-brush, which accident was the starting-point for the subsequent septicemia. Dr. Sweetnam was graduated from Toronto University in 1881 and also from Victoria University. He was 42 years of age and at the time of his death was professor of clinical surgery at Toronto University and surgeon to the Toronto General and St. Michael's hospitals.

LONDON LETTER.

Death of Sir William MacCormac.

The sudden death of Sir William MacCormac, which took place on December 4, has brought to a close a most distinguished career and removed the most prominent social figure in the profession. It is feared that the sad result was due to fatigue and exposure during his service as consulting surgeon to the Army in South Africa. He was attacked with dysentery and ever since his return suffered from lumbar pain, abdominal tenderness and loss of flesh. To escape the London fogs he journeyed to Bath, where he was taking immersion baths, from which he had derived much benefit in former years. At 7:30 a. m., while sitting up in bed and taking a cup of coffee, he suddenly put his hand to his heart with an expression of pain and expired. Sir William MacCormac was born at Belfast in 1836; his father, Dr. Henry MacCormac, was a well-known medical practitioner in the town and one of the pioneers of the open-air treatment of consumption. Young MacCormac studied medicine at Queen's University in Ireland and in 1864 became a fellow of the Royal College of Surgeons in Ireland. He was appointed surgeon to the Royal Belfast Hospital and during six years' tenure made injuries of joints a special study. For many years he was a member of the senate of the Queen's University in Ireland and examiner in surgery. In 1870 he volunteered his services for the aid of the French wounded in the Franco-German war. He joined the Anglo-American ambulance, a body consisting of eight English and eight American doctors, over which Dr. Marion Sims of New York presided. On the latter's return to America MacCormac was appointed surgeon-in-chief. Each day more than 100 major operations were performed. On one day MacCormac himself performed several amputations of the leg, thigh, forearm and arm; he excised the shoulder and elbow joints, and performed partial resections of the upper and lower maxillæ and of nearly the whole ulna, to say nothing of removal of bullets and pieces of shell from various parts of the body. On his return to England he published his experiences in a work entitled, "Recollections of an Ambulance Surgeon," which enjoyed great popularity and was translated into all the European languages and into Japanese. In 1883 he was elected a member of the council, and in 1896 became president. He was re-elected president four times and thus held the office for the unprecedented period of five

years. This was no doubt largely due to his great social success. He was a *persona grata* with the King and in great favor with all ranks of society and with the profession. His presence was most imposing; he was probably the tallest man in the profession, standing 6 feet 3 or 4 inches, and had handsome aquiline features. His genial manners and generous disposition no doubt contributed largely to his social success. He was described as "a big-bodied and big-hearted Irishman." The remarkable success of the centenary celebration of the college last year and the many brilliant ceremonies were largely due to his initiative and influence. Largely through his aid were gathered together the Prince of Wales, the Premier, Earl Roseberry and the most eminent representatives of surgery in the world, who received the honorary fellowship of the college at his hands. In 1881, when the International Medical Congress met in London, he was appointed secretary-general. His services were recognized by the government, which conferred on him knighthood. His twenty years' work at St. Thomas' Hospital was most fruitful and he was a very successful teacher. He was one of the first to perform laparotomy for rupture of the bladder, and was an early and strenuous advocate of Lister's antiseptic system. In 1897 he was made a baronet. In 1898, in consequence of his unique experience of war surgery, the government gladly availed itself of his services as consulting surgeon in the South African war. His most important work was "Surgical Operations," which was beautifully illustrated by drawings from the pencil of his colleague and friend, the late Mr. Willam Anderson, surgeon to St. Thomas' Hospital. The number of foreign honors conferred on him were very great; he was decorated by almost every European government. His wife survives him, but he leaves no children.

Departure of Mr. Jonathan Hutchinson for South Africa.

Mr. Jonathan Hutchinson, who has performed in a long life the work of many men, is still hale and remains as indefatigable a student and investigator as ever. He has just astonished all his friends by undertaking a journey to South Africa for the purpose of studying leprosy and any other medical or biological phenomena which may come in his way. His principal object to investigate leprosy with reference to his fish hypothesis which, like all his doctrines, he holds with the utmost pertinacity even in the face of almost universal opposition. His opponents instance South Africa as a striking example of the breakdown of the fish theory. They say the Kaffirs abominate fish and yet suffer from leprosy. Mr. Hutchinson will first visit Robbin Island, which is near Cape Town, and is devoted to the segregation of lepers, and will interrogate the lepers himself.

Excision of the Gasserian Ganglion for Neuralgia.

At the Clinical Society Mr. Jonathan Hutchinson, Jr., reported the results of five cases in which he had excised the Gasserian ganglion, four of the patients being shown at the meeting. The operation had been performed in one case four years, in two, three years, and in one case two years previously. In not one had there been the slightest recurrence of the neuralgia. He urged that the temporal route should alone be employed to gain access to the ganglion and quoted one of his cases in which the operation from below by the pterygoid route (Rose's method) had been previously performed by another surgeon. The operation had been carried out in two stages, and it was believed that the ganglion had been at any rate in part removed. The return of the neuralgia worse than before and the imperfect anesthesia had raised doubt as to this, and at the final operation by Krause's method it was proved that the ganglion was quite intact and that the base of the skull had been penetrated outside the foramen ovale. Such a case well illustrated the fallacies attending operation by the pterygoid route. He pointed out that in severe epileptiform neuralgia of the fifth nerve the ophthalmic division was effected in only one-fifth of the cases, that probably in some of these the involvement of the first division was in a sense reflex and would be cured by removal of the second and third divisions with the corresponding part of the ganglion, leaving the ophthalmic trunk untouched. Many cases prove the correctness of this view, and he did not know of a single one in which after this course had been thoroughly carried out the neuralgia had returned in the ophthalmic division. If the latter were spared the eye ran no risk, whilst other complications, such as injury to the oculomotor nerves and the cavenous sinus might be avoided with comparative ease. He instanced one of his cases in which, after complete removal of the ganglion, the corresponding eye had become inflamed and required excision after several months had elapsed. In his later cases he had deliberately avoided cutting the ophthalmic part. As regards the details of the excision it was probably better to use a large trephine and cutting forceps—without subsequent replacement of bone—than to turn down a flap and overlying tissues. It was not always necessary to tie the meningeal artery, especially if the lower part of the ganglion alone were dealt with. Hemorrhage was lessened by keeping the patient during the whole operation in a sitting position. An electric head lamp was essential. The use of the curette to break up the ganglion was strongly deprecated. Intra-dural division of the fifth nerve was far more dangerous than extra-dural excision of the ganglion. Dr. Taffany's statistics of 108 cases, with a mortality of 23 per cent., did not at all represent the actual risk of the Hartley-Krause operation, for amongst them were included cases operated on by many methods, including the dangerous intra-dural one, and such needlessly severe methods as that advocated by Doyen. The latter surgeon had lost two out of three of his cases from the operation. The mortality of the operation by the temporal route in skilled hands was probably under 10 per cent., and so lasting were the results that without doubt in the future most of the operations on the main branches of the fifth nerve for severe neuralgia would be abandoned in its favor. He urged that the victims epileptic from neuralgia should not be left to develop suicidal tendencies or to poison themselves with morphia before being given the chance of a permanent cure by the operation.

Married.

A. S. Yenni, M.D., to Miss Marie A. Lafitte, both of New Orleans, La., November 20.

Horace B. Haddox, M.D., to Miss Mary Lee Waters, both of Gaithersburg, Md., December 3.

Herman Oechsner, M.D., New Orleans, La., to Miss E. Edith Appel, Slidell, La., October 23.

B. A. Terrett, M.D., Natchitoches, La., to Miss Edna Lillian Trist, of New Orleans, La., November 16.

Henry A. Blair, M.D., San Antonio, Texas, to Mrs. Lily C. Edmondson, at St. Louis, Mo., December 4.

Martin L. Mayland, M.D., to Miss Josephine Olivette Sullivan, both of Faribault, Minn., November 30.

U. S. G. Hughes, M.D., Kansas City, Mo., to Miss Dora Elizabeth Brown of Topeka, Kan., December 5.

J. W. Simmons, M.D., Peaster, Texas, to Miss Maude Wilcutt, of Lewisburg, Ky., at Bowling Green, Ky., December 7.

Claude B. Calbreath, M.D., Cleopatra, Mo., to Miss Mollie Boland, of Lucerne, Mo., at Kansas City, Mo., November 27.

Frank N. Freemire, M.D., Chester, Iowa, to Miss Josie Johnson, of Fountain, Minn., at Chester, Iowa, November 27.

Willard L. Matthews, M.D., to Miss Bessie Hendricks, both of Martinsville, Ind., at Lawrenceville, Ill., December 4.

Frank Webster Jay, M.D., Chicago, late major and surgeon, U. S. V., to Miss Harriet Staples, daughter of the late Dr. George M. Staples, of Dubuque, Iowa, December 10.

Deaths and Obituaries.

John H. Sears, M.D. Medical College of the State of South Carolina, Charleston, 1852, a member of the American Medical Association; one of the founders and ex-president of the Texas State Medical Association; one of the founders and several times president of the Waco Medical Association, died at his home in Waco, Texas, after a lingering illness, December 4, aged 75. He was a native of Virginia, and served in the Civil war as surgeon of the Thirty-second Texas Cavalry and later as division surgeon. The medical men of the city met on the day of Dr. Sears' death, and adopted the following resolutions: "We, the medical profession of Waco, are called upon to mourn the loss of one of our beloved profession, whom we have in years of professional association with him learned to love and honor, Dr. J. H. Sears. Therefore, we, the medical profession of Waco, sincerely mourn our loss of both dear friend and worthy brother, whose daily professional courtesies we should all strive to emulate, thereby adding both trust and confidence to our standing with our brethren in the profession and the

public whose sympathies has so sweetened his declining years: Be it Resolved, That we tender our kindest sympathy to his family in their great bereavement, and that we, as a body, show our love and sympathy by attending the funeral in a body."

William J. Van Eman, M.D. Medical College of Ohio, Cincinnati, 1875, prominent as a physician in Kansas, a member of the local, state and the American Medical associations, died at his home in Leavenworth, Kas., December 9, from a septic wound of the hand, after an illness of three weeks, aged 52. In the early part of his career he was an acting assistant surgeon in the Army and served throughout the Sitting Bull campaign with General Miles. In 1880 he settled in Leavenworth, where he afterward resided and practiced.

John E. Beers, M.D. University of Georgetown, Washington, D. C., 1864, prominent as a practitioner of Tompkins County, N. Y., an esteemed citizen, sometime assemblyman, a surgeon during the Civil war, and for many years a member of the Pension Examining Board, died suddenly from apoplexy at his home in Danby, December 5, aged 61. For one hundred and four years, Dr. Beers, his father and his grandfather had practiced in Danby.

Edward B. Zier, M.D. University of Louisville, Ky., 1878, a native of New Albany, Ind., but for more than twenty years a practitioner of Minneapolis, a member of the legislature in 1894, died at his home in Minneapolis, December 9, after an illness of many months, from Bright's disease, aged 44.

William White Harris, M.D. Jefferson Medical College, Philadelphia, one of the most honored citizens of Wilmington, N. C., and a veteran of the Civil war on the Confederate side, died at the residence of his daughter in Wilmington, December 7, from heart failure due to acute indigestion, aged 77.

Josiah W. Pearson, M.D. University of Vermont, Burlington, 1883, a practitioner of Providence, R. I., died at a sanatorium in that city, December 2, after a brief illness from heart failure after an operation for appendicitis, aged 45.

Lesslie M. Sweetnam, M.D. Toronto University, 1881, a resident of Toronto, died December 11, at Johns Hopkins Hospital, Baltimore, from sepsis following an operation several weeks before.

Peter Austin, M.D. Jefferson Medical College, Philadelphia, 1850, who had practiced medicine in Carrollton, Mo., for more than forty years, died at his home in that place, December 7.

Robert McLearn, M.D. New York University, 1880, died at Fredericton, New Brunswick, November 29, after an illness of ten days, from bronchitis and heart trouble, aged 47.

Arthur Watters, M.D. Laval University, Quebec, 1878, a physician of Quebec, and surgeon of the Ninth Regiment, died at his home in Quebec, December 5, after a long illness.

Simeon J. Shaw, M.D. Starling Medical College, Columbus, Ohio, 1879-1880, a practitioner in Great Bend, Kas., died from heart disease at his home in that city, December 10.

Ada Smith, M.D. Woman's Medical College of Georgia, Atlanta, a native of Greenfield, Ind., died from tuberculosis at Phoenix, Ariz., December 8, aged 32.

M. S. Stahl, M.D. Rush Medical College, Chicago, 1865, died at his home in Guthrie, December 7, aged 75.

J. L. Sharp, M.D. Tulane University, New Orleans, La., at Blanchard, La., November 15.

Correspondence.

Passing of Sectarianism in Medicine—The Position of the New York State Medical Association.

NEW YORK CITY, Dec. 10, 1901.

To the Editor:—I was very much interested in an editorial from the St. Paul *Medical Journal*, which appeared in THE JOURNAL, November 16, 1901, entitled "The Passing of Sectarianism in Medicine," and I would like to call the attention of your readers to the advanced position taken by the reorganized New York State Medical Association on this subject. The only requirements for membership in this organization are that a physician shall be legally registered, shall be in good standing, and a resident of the State of New York. These requirements would seem to cover the points made in the editorial to which I have already referred, allowing, as they do, any legally registered physician in this state, *no matter* from *what school* he may have graduated, to become a member of the Association, provided only that the applicant calls himself simply a physician, without making use of any qualifying adjective, and does not belong to any organization which is avowedly hostile to the general medical profession. To make its position on this point perfectly clear, the Council and Fellows of the New York State Medical Association at its annual meeting held in this city in October last, passed the following resolution:

"WHEREAS, There exists widespread misunderstanding as to the interpretation of Section 1, Art. IX of the by-laws of the New York State Medical Association, it is hereby declared that the words, 'Physicians in good standing,' have been, and are held to mean, under the code of ethics of the American Medical Association, legally registered physicians who make no claim to base their practice upon exclusive dogma, and who maintain no professional relation with organizations or institutions representing such dogma."

Yours truly, FREDERICK HOLMES WIGGIN, M.D.,
Formerly Secretary, the New York State Medical Association.

Miscellany.

The Osteopathy Decision in Ohio.—The following is the substance of the facts regarding the sweeping decision of the Supreme Court in the test case of the State against Henry H. Gravett, of Darke County, as given by our correspondent:

"Doctor" Gravett was indicted for practicing osteopathy without first having complied with the law of Feb. 27, 1896, as amended April 14, 1900. The original act requires all persons who contemplate practicing medicine to submit to an examination before the State Board of Medical Examiners. In a case brought under that section the State argued that the system of rubbing or kneading the body known as osteopathy, is an "agency" within the meaning of the statute, but the court held that the practice of medicine means the administering of a drug or medicine that is intended to produce an effect by its own potency. Two years ago the law was amended and an attempt made to give a broader definition of the term "practice of medicine." Under this act, any "appliance, application, operation, or treatment of whatever nature for the cure or relief of any wound, infirmity," etc., is called the practice of medicine. The amendment excluded from the requirements of the original act requiring examination "any osteopath who holds a diploma from a legally chartered and regularly conducted school of osteopathy . . . . wherein the course of instruction requires at least four terms of five months each in four separate years, provided that such osteopath shall pass an examination satisfactory to the State Board on the subjects of anatomy, physiology, chemistry and physical diagnosis." The Supreme Court, in overruling the exceptions to the decision of the Common Pleas Court, finds that the system of kneading, commonly known as osteopathy, is comprehended within the practice of medicine defined by the amendment of two years ago, and that an osteopath may be required to conform to such reasonable standard respecting qualifications as the General Assembly may prescribe, but an enactment which discriminates against osteopaths by requiring them to hold diplomas from a college which requires four years of study as a condition to their limited certificates which will not permit them to prescribe drugs or perform surgery, while not requiring such time of study from those contemplating the regular practice as a condition to their obtaining unlimited certificates, is, as to such discrimination, null and void. The decision was unanimous.

New Instruments.

A NEW OPTHALMOSCOPE,

COMBINED WITH WHICH THERE IS A PLANE MIRROR FOR RETINOSCOPY; INTENDED AS A POCKET INSTRUMENT FOR OPHTHALMOLOGISTS AND PRACTITIONERS.

BROWN PUSEY, M.D.
LATE HOUSE SURGEON, NEW YORK EYE AND EAR INFIRMARY.
CHICAGO.

This instrument is offered primarily to meet the demand for an ophthalmoscope that can be carried conveniently in one's pocket without a box or case. It consists of a frame with two arms, which swing on a hinge-joint. The arms carry two mirrors, which are so placed that when the instrument is closed, the mirrors lie face to face, and are thus protected from injury and dirt. When the instrument is open one arm acts as a handle for the other. In the joint there is a spring bolt, which fastens the joint tightly when the mirrors lie

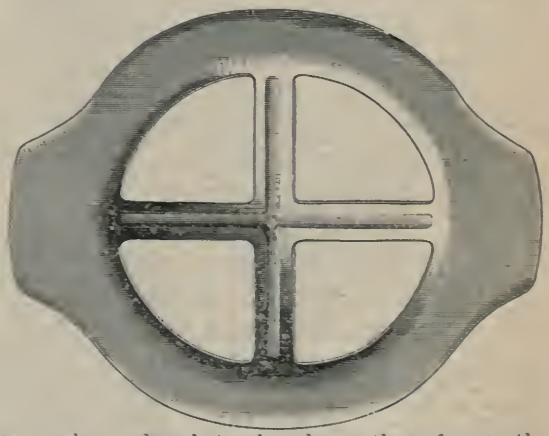
Open.

face to face, and also locks the joint when the instrument is open; this spring bolt is loosened by pressing a little knob. The arms are nickel-plated; on the outside this plating has a high polish, on the inside it has a dull finish, so that this metal part will not reflect light. The parts which form the backs of the mirrors are lacquered black.

The mirrors are circular, with a diameter of 1 3-16 inches; the concave mirror has a focal length of 11 inches. Back of the concave mirror, a wheel is placed in which there are five lenses, a +2 D., a +4 D., for use in making examinations by the indirect method, a +8 D. for use in examining on levels in front of the retina, a —3 D. for the unskilled user, who accommodates when making a direct examination, and a —10 D.

Closed.

for examining myopes; there is also a hole in the wheel. The silvering of the mirrors at the center is removed in a circular space of 3/32 of an inch in diameter; this arrangement was observed particularly because of the advantages offered by such mirrors for retinoscopy.



The completeness of the instrument will suggest itself. It is not a refracting ophthalmoscope with its many combinations of lenses, and, indeed, who in the present day of accurate refraction wants a refracting ophthalmoscope? The instrument is not intended to take the place in the ophthalmologist's office of his Morton. It is so compact that it weighs less than two ounces; it is ¼ inches thick, 2⅝ inches long when closed. It is solid, substantial and of neat finish, and can be sold at a very low price—an advantage which will be particularly considered by students.

VACCINATION SHIELD.

C. P. FRANKLIN, M.D.
PHILADELPHIA.

After repeated and increasing trouble with irritated, inflamed and infected arms due to the existing forms of vaccination shield, the idea of what a vaccination shield should be has, during the course of the last ten thousand vaccinations, been gradually evolved, until the form described below, and shown in the illustration has been reached, and the writer feels that he has produced a shield which will meet all the conditions properly imposed upon such an important accessory to a perfect vaccination. A shield may be a source of comfort, protection and satisfaction, or it may be productive of distress, irritation and even infection if not suitable. The objections urged against the present forms in use have been obviated in that described below.

The shield is made of aluminum, 6 centimeters in diameter to the outer edge of its flange, which latter is curved so that

it presents no sharp edges but a broad smooth surface to the arm, and is extended at each end into a tab or projection by which it is fastened to the arm with short, narrow strips of plaster. The central part, or dome, is 4.5 centimeters in diameter, and is raised above its base one centimeter, being composed of two ribs, crossing at right angles, each rib being strengthened by a beading or groove, so that it will stand any ordinary pressure. The advantages of this shield are: lightness and durability; adaptability, as being of annealed metal it can be readily curved to fit the contour of the part vaccinated; cleanliness, as it can be washed and sterilized as often as necessary; non-irritating, as, owing to its large openings and air spaces, it does not confine the wound, and is accessible for inspection without disturbing it.

Association News.

The Committee on National Legislation.

The Committee on National Legislation has sent the following communications to the secretaries of the different State Medical Societies and hereby requests any such secretary who fails to receive his notice, to communicate at once with the Committee, through its chairman, H. L. E. Johnson, M.D., Washington, D. C.

WASHINGTON, D. C., Dec. 2, 1901.

My Dear Doctor:—On behalf of the Committee on National Legislation of the American Medical Association, I earnestly request you to send at your earliest opportunity the names and addresses of the delegate and alternate who are to represent your State Medical Society at the Third Annual Conference at Washington, D. C., this winter.

When you furnish me their names, I will notify them and you of the date of the proposed conference. Please refer to the Second Annual Report of this Committee and the minutes of the Second Annual Conference which appear in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of June 8, 1901, on pages 1635 and 1636, respectively.

Please acknowledge the receipt of this communication and thereby facilitate the work of this Committee, and greatly oblige.

Yours very truly, H. L. E. JOHNSON, M.D., Chairman.

WASHINGTON, D. C., Dec. 2, 1901.

My Dear Doctor:—At the meeting of the Second Annual Conference of the Committee of the American Medical Association on National Legislation, with the delegates from the various State

Medical Societies, held at Washington, D. C., February 20 and 21 last, the Conference by unanimous vote directed me to send to the secretary of each State Medical Society in affiliation with the American Medical Association the following:

The American Medical Association has provided in its Constitution for a Committee on National Legislation whose duty it shall be to keep informed on all matters of medical legislation arising in the National Congress, and present to that body the wishes and views of the American Medical Association, and the regular profession, with respect to these various measures proposed. It is the duty of this committee to oppose all medical measures introduced in the House or Senate which are deemed obnoxious or hurtful to the interests or wishes of the medical profession of the United States, and to favor the passage of such medical matters proposed in said Congress which are considered wise, just and proper by your Committee on National Legislation. In order to learn the wishes and views of the general profession on the medical matters proposed, and strengthen the representations of the Committee on National Legislation before Congress and its various Committees, the American Medical Association requests the various State Medical Societies, the Medical Department of the Army, Navy, Marine-Hospital Service and the U. S. Animal Industry, to appoint, each, one delegate and one alternate to meet the Committee on National Legislation in annual conference at Washington, D. C., discuss the various medical matters pending before Congress, and when necessary to appeal to the National Congress as a conference, to pass or defeat medical measures which may be approved or disapproved at the annual conference. The American Medical Association wishes to emphasize before the Congress of the United States and the various State Legislatures, the importance and high standing of the medical profession of the United States, and impress upon these bodies the necessity and propriety of hearing and considering the wishes of the regular profession in matters of pending medical legislation. It is duly appreciated that legislators have been in the habit of hastily passing medical laws and ordinances without consulting the views or opinions of the scientific medical profession. The Legislative Committee with the co-operation of the State Medical Societies, through their delegates in joint conference assembled, annually, at Washington, will unqualifiedly raise the standard of medical views and opinions with respect to State and National medical legislation.

The Committee on National Legislation points with pride to its last annual report to the American Medical Association published in THE JOURNAL of June 8, beginning on page 1635, from which I quote, among other things: "We are pleased to report that as a result of the combined efforts of your Committee, and the delegates to the Annual Conference, the obnoxious Senate Bill No. 34, entitled, 'For the further prevention of cruelty to animals in the District of Columbia,' known as the Antivivisection Bill, has been defeated, and rendered practically impossible of passage in the future. As a result of the Second Annual Conference held at Washington, February 20 and 21, 1901, we have the honor to report the passage of Senate Bill No. 4171, entitled, 'An act granting additional quarantine powers and imposing additional duty upon the Marine-Hospital Service,' and the defeat of Section 150 H. R. Bill No. 13,423 of the codification of postal laws. This section, if it had become a law, would have cost the American Medical Association about $30,000 extra in postage in connection with the distribution of THE JOURNAL to our members and subscribers. We observe with great satisfaction and hope for future National influence of the American Medical Association, and the Committee on National Legislation that the Medical Societies of the several States and Territories are beginning to appreciate the importance of the Annual Conference, and the necessity of State co-operation in matters of medical legislation, both local and National, as evidenced by the increased attendance at the Second Annual Conference which was held at Washington, D. C., in February last, at which conference the delegates in session appointed a standing committee of the Second Annual Conference with full power to represent them and act *ad interim* in all medical matters arising in the Congress of the United States."

The American Medical Association desires to impress upon the several State Medical Societies the great importance, and the National weight of the annual conferences, and to this end urges each State Medical Society to appoint promptly a delegate and alternate to each annual conference. In order to facilitate the labors of the Committee on National Legislation the secretary of each State Society is requested to send to the Chairman of the Committee on National Legislation the names and addresses of their delegate and alternate duly appointed. The Third Annual Conference will be called before the close of the present session of Congress, possibly the latter part of February or the first of March, 1902.

Very truly yours,

H. L. E. JOHNSON, M.D., Chairman,

Committee on National Legislation, American Medical Association.

New Members.

The following is a list of new members for the month of November, 1901:

ALABAMA.

Law, W. L., Montgomery.
McNelli, R. B., Jenison.
Stubbs, G. H., Birmingham.

CALIFORNIA.

Abrams, Albert, San Francisco.
Couey, E. J., Fresno.
Eichler, A., San Francisco.
Fehleisen, F., San Francisco.
Shank, G. A., Benicia.
Morton, A. W., San Francisco.

CONNECTICUT.

Wade, J. A., Danbury.
Judson, W., New Haven.

GEORGIA.

Burford, R. E. L., Brunswick.
Dozier, Jr., R. T., Milledgeville.
Minter, H. G., Jakin.

ILLINOIS.

Barnes, C. L., Chicago.
Miller, J. E., Chicago.
Naughton, M. T., Chicago.
Noble, R. M., Chicago.
Roberts, T. E., Chicago.
Ransom, P. W., Rockford.
Wagner, G. W., Chicago.
Whitfield, G. W., Chicago.
Willard, W. G., Chicago.
Achard, H. J., Roselle.
Campbell, Jas., Elgin.
Daly, V. M., Pontiac.
Denby, J. P., Carlinville.
Diller, F. S., Roberts.
Elion, C. J., Altona.
Fish, W. H., Baylis.
Galbraith, C. M., Carbondale.
Jennings, J. F., Scotland.
Keller, U. S. G., Warren.
Lane, G. H., East St. Louis.
Matheny, Z. E., Pesotum.
Starke, C. V., Rockford.
Watterson, W. H., N. Chicago.
Hughes, Thos., Chicago.
Low, J. R., Chicago.

INDIANA.

Bowen, J. F., Rushville.
Boor, W. F., Newcastle.
DuPuy, C. M., Riley.
Graessle, G. G., Seymour.
Jones, G. B., Rushville.
Loring, D. J., Valparaiso.
Marsh, J. L., Brownsburg.
Bowen, J. F., Rushville.
Day, Albert, Crothersville.
Putnam, W. E., Whiting
Reynolds, F. M., Montpelier.
Rowland, Geo., Covington.
Shafer, J. W., Morocco.
Stork, J. W., Evansville.
Smoot, D. B., Glen Dale.
Smith, I. F., Arlington.
Tucker, F. A., Noblesville.

INDIAN TERRITORY.

Davis, C. Howard, Checotah.
Gardner, D., Lehigh.

IOWA.

Societies.

Montgomery County (Ohio) Medical Society.—At the annual meeting of this Society Dr. John S. Beck, Dayton, was re-elected president and Dr. Horace Bonner, Dayton, secretary.

Summit County (Ohio) Medical Society.—This Society held its annual meeting at Akron, December 3, and elected Dr. Charles E. Held, president; Dr. L. B. Humphrey, vice-president; Dr. Edward A. Montenyohl, secretary, and Dr. Charles E. Norris, treasurer, all of Akron.

St. Louis Academy of Medicine.—At the annual meeting of this Academy the following officers were elected to serve one year, from December 11: Dr. Augustus C. Bernays, president; Dr. J. William Williamson, vice-president; Dr. G. Harry Nicks, second vice-president; Dr. Alfred Roulet, secretary, and Dr. G. Howard Thompson, treasurer.

Crow River Valley Medical Society.—The twenty-first meeting of this Society was held in Litchfield, Minn., December 11. Papers were read by Drs. Harry Morrel, Slayton; Henry E. Cassel, Litchfield; Frank M. Archibald, Atwater, and James W. Robertson, Litchfield. The Society was entertained by Dr. Wiley E. Chapman, Litchfield.

Brazos Valley (Texas) Medical Association.—The twelfth annual convention of this Association was held at Bryan, November 12 and 13. Resolutions were passed on the deaths of Drs. Ernest A. Thompson, Navasota, and R. K. Fountain, Jones Prairie. The usual banquet was held and Marlin selected as the place for the semi-annual meeting in May, 1902.

Butler County (Ohio) Medical Society.—At the annual meeting of this Society held at Middletown, December 4, Dr. James E. Torrence, Oxford, was elected president; Dr. Edward H. French, Hamilton, vice-president; Dr. John R. A. Grafft, Hamilton, secretary, and Dr. Francis M. Fitton, Hamilton, treasurer. Dr. Joseph Eichberg, Cincinnati, made an address on "Latent Endocarditis."

Rock County (Wis.) Medical Society.—The annual meeting of this Society was held December 6, at Janesville. The following officers were elected: Dr. Samuel B. Buckmaster, Janesville, president; Dr. Michael A. Cunningham, Janesville, vice-president; Dr. George W. Fifield, Janesville, secretary; Dr. Ranson W. Edden, Janesville, treasurer, and Dr. Frank B. Farmsworth, Janesville, censor.

Delaware County (Ind.) Medical Society.—At the last meeting of this Society for the year, held at Muncie, "Food and Drug Adulterations" was the subject for discussion. Dr. James N. Hurty, secretary of the State Board of Health, was present. Dr. Henry C. Burcham, Albany, was elected president; Dr. Arthur T. Kemper, Muncie, vice-president, and Dr. Ulysses G. Poland, Muncie, secretary and treasurer.

Calhoun County (Mich.) Medical Association.—The twenty-fifth annual meeting and banquet of this Association was held in Albion, December 3. The following officers were elected: Dr. George C. Hafford, Albion, president; Drs. Louis S. Joy, Marshall, and James H. Reed, Battle Creek, vice-presidents; Dr. William H. Haughey, Battle Creek, secretary, and Dr. Richard M. Olein, Battle Creek, treasurer. The next meeting will be held in Battle Creek, March 4, 1902.

Southeastern Iowa Medical Society.—The thirty-first annual meeting of this Society in Burlington, November 21, was one of the most largely attended and successful in the history of the Society. The election of officers resulted as follows: Dr. Charles F. Wahrer, Fort Madison, president; Drs. George Kinney, Burlington, and William S. McClellan, Morning Sun, vice-president, and Dr. Carl Stutsman, Burlington, secretary-treasurer. The next meeting will be held in November, 1902, in Fairfield.

Buffalo Academy of Medicine.—The last stated meeting of the Medical Section was devoted to clinical reports. A case of Little's disease was reported by Dr. Irving M. Snow; one of Friederich's ataxia, by Dr. Dewitt H. Sherman; one of microcephalus, by Dr. L. W. Schrotten, and one of congenital idiocy, by Dr. Julius Ullman. Dr. Charles H. Frazier of Philadelphia, Pa., addressed the Surgical Section of the Academy on "The Division of the Sensory Root of the Trigeminus for the Relief of Tic Douloureux—An Experimental, Pathological and Clinical Study with a Preliminary Report of One Surgically Successful Case."

Tri-County Medical Society of the State of California.—A number of the physicians of Santa Cruz, San Benito and Monterey Counties, met December 3, in Watsonville, Santa Cruz County, and organized, with seventeen charter members. The following officers were elected: Dr. Thomas C. Edwards, Salinas, Monterey County, president; Drs. Henry C. Whiting, Santa Cruz, Santa Cruz County; Nat. Green, Watsonville, Santa Cruz County; Auburn M. Stafford, Monterey, Monterey County, and James H. Tebbetts, Hollister, San Benito County, vice-presidents, and Dr. Saxton T. Pope, Watsonville, Santa Cruz County, secretary-treasurer. At the close of the meeting the physicians of Watsonville entertained their professional brethren at a banquet.

Northwest Arkansas Medical Society.—The annual meeting of this Society was held in Fayetteville, December 3. The Society is in flourishing condition. The following papers were read: By Dr. William P. Illing, Little Rock, "The Use of Tropa-Cocain in Spinal Anesthesia"; by Dr. L. Kirby, Harrison, "A Case of Ovariotomy"; by Dr. Joseph T. Clegg, Siloam Springs, "Abortion"; by Dr. Charles H. Cargile, Bentonville, "Dysmenorrhea"; by Drs. E. H. Highfill, Hoover, and George W. Cale, Jr., Springfield, Mo., "Case Reports"; by Dr. John B. Bolton, Eureka Springs, "The Profession"; by Dr. James H. Lindsey, Bentonville, "A Case of Compound Dislocation of the Elbow Joint"; by Dr. Asbury J. Vance, Harrison, "A Case of Fracture of the Skull, with Loss of Brain Substance"; by Dr. David C. Summers, Elm Springs, "Syphilis"; by Dr. Rufus S. Rice, Rogers, "Diphtheria and Its Treatment"; by Dr. Herbert Moulton, Fort Smith, "Shot Injuries of the Eye"; Dr. Thomas W. Hurley, Bentonville, "Veratrum Viride," and Dr. William B. Welch, Fayetteville, "Dirt and Its Dangers." Dr. Thomas W. Hurley, Bentonville, was elected president; Dr. Harvey D. Wood, Fayetteville, vice-president; Dr. Frank B. Young, Springdale, secretary; Dr. Rufus S. Rice, Rogers, assistant secretary, and Drs. William B. Welch, J. Young, and Rufus S. Rice, committee on credentials. The next meeting will be held at Rogers, in June next.

Marion County (Ohio) Medical Society.—The annual social session and banquet of this Society, December 10, in Marion, was held in the parlors of the Hotel Reber and the banquet was served in the spacious dining-room of the hotel. Dr. O. W. Weeks was the toastmaster, and in assuming his duties responded to the toast, "The President of the United States." Dr. B. L. Milliken, Cleveland, responded to "The Medical Profession." Dr. H. C. Uhler toasted "Our Guests," and Dr. C. A. L. Reed responded. Dr. J. A. Kimmell, author of the Kimmell Bill to regulate the Practice of Medicine in Ohio, toasted "The Ohio State Medical Society." Dr. C. E. Brush, president of the State Society, and Dr. P. Maxwell Foshay, secretary of the Society, responded.

Dr. C. A. L. Reed, Ex-President of the American Medical Association, closed his address before the social session, on "Currents and Counter-Currents in the Profession," with the following:

> It seems, from evidence that has recently come from within the army itself, that the medical department has not only been degraded, but that it is practically without authority. This was strikingly, indeed, tragically, illustrated during the recent war. A commandant—and I have no hesitancy in saying that I mean General Brooke—was in charge of more than a quarter of the entire army. His command was made up of the flower of American manhood, and was encamped at a health resort. He, however, in violation of the precedent of the usually cultivated and competent gentlemen of the line, but acting under the permission of existing army regulation, not only set aside recommendations of his sanitary officers, but, by personal example, incited his men to violate the most fundamental sanitary laws. The result was what might have been expected. Of the more than 50,000 men in his command, 12,000 were invalided, while nearly 1000 died from preventable causes. If, in an active military operation, General Brooke had ignored the advice of his scouts and had led his command into an ambush, with similar disastrous results—12,000 wounded and 1000 killed—he would have been court-martialed, and, doubtless, dismissed from the service. The regulations, however, I am advised, fix no responsibility for this unparalleled calamity, the enormity of which is only beginning to be understood. It is not surprising that efforts have been made to suppress knowledge of it. I am told that General Brooke himself threatened to court-martial a witness who offered testimony on this point. I am also advised that the Army Investigating Commission, in the interest of public decency, omitted from its public report much testimony on this phase of the conduct of the war. . . . We of America may blush, but the scandal is ours. The voracious historian of military horrors must classify "Brooke's Blunder" with the "Black Hole of Calcutta." The Congress, at the present session, is to be asked to intervene in this matter—a matter that appeals to every soldier, to every home that furnishes a soldier, to every patriot that is proud of the army, to every citizen that is actuated by the ordinary impulses of humanity.

Dr. P. Maxwell Foshay addressed the social session on the importance of all legal practitioners in all states and territories of the Union, of uniting in the organization of medical societies in their respective counties where there was no organiza-

tion, on the plan adopted by the American Medical Association that the barriers between the schools might be broken down and that all practitioners might unite upon the basis of a common cause for the elevation of the science of medicine to a higher standard; also that the profession might receive a higher recognition in the military service of the United States.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held Nov. 26, 1901.

DR. D. W. MONTGOMERY in the Chair.

Ankylostomiasis.

DR. L. A. KENGLA presented a case of ankylostomiasis as follows: J. A. H., aged 34, male, single, height 5 feet 11 inches, weight 138 pounds, was discharged from the Army in April as well and capable of duty. At age of 18 had scarlet fever, which left him a little deaf, otherwise very healthy until a year after enlistment, which occurred in May, 1898. Was sent to the Philippines in November, 1898, in perfect health, weight 160 pounds; began active service on arrival throughout Northern Luzon; was forced to drink from stagnant pools and of water wherever found. About August, 1900, complained of inability to march; of weakness with fever, which was variable as to time of appearance and intensity. Bowel disturbances with diarrhea became more frequent and severe; symptoms would become intensified and then improve. He continued in the field, growing pale and losing flesh. Diagnosis of malaria was made and treatment given accordingly. There was no improvement, and about Nov. 15, 1900, a severe attack of diarrhea set in with increased weakness, prostration and great pallor. He was sent to the hospital. His evacuations ranged from 6 to 25 in a day, loose and soft, coated with mucus, with no pain and no blood except on March 15, when he had rather a free hemorrhage from bowels and another slight one, May 18. There was an uncomfortable sensation in abdomen of soreness, distention and puffiness. His temperature was variable, reaching 106, and falling rapidly to 99, and seemed to depend upon character and quantity of food; solids caused much distress, uncomfortable feeling in epigastrum and tenderness; increased the frequency of stools and raised the temperature. As a rule the number of passages did not keep pace with variations of temperature. The patient grew weak, greatly depressed and melancholic. Appetite was variable, sometimes ravenous; always had desire for food, but was afraid of the consequences. He had an intense longing for gritty substances, sand, chalk, clay, etc. There was dizziness, dyspnea on exertion and palpitation of heart. During the months of December and January all symptoms increased, especially pallor, weakness and exhaustion. Bowel movements were same in character and consistency; average about same as in November, of brown, gray or ashy color, with no griping or tenesmus. The amount of urine remained about normal, though the color changed with varying conditions. Temperature ran from 99 to 104, pulse 120 or more; sleep during this time was fairly good. Anemia was deep and marked. In January edema of legs appeared; they became badly swollen, and to a less degree also face and hands. All other symptoms slightly increased. He noticed fatty tumors at various parts of body in January. Left Manila February 17, presumably dying. The journey across the Pacific improved his general condition a little; his diarrhea, digestive disturbances and anemia remained nearly the same. He was under treatment for several weeks at the Presidio, and was finally voluntarily discharged. When the author saw him on May 18, his condition was as follows: Patient fairly well nourished; extremely pale; complained of severe diarrhea, 10 movements that day; great weakness and exhaustion; dyspnea; palpitation on exertion; temperature 103; pulse 125; respiration 24. Inspection showed no sign of emaciation; adipose tissue was in good quantity and well distributed; skin was of slightly dull muddy color, tinged perceptible yellow; eye, sclera and conjunctiva were pale; pupils were equal, no dilatation; tongue was coated, flabby and indented; muscles of body were well developed, slight edema at ankles and very slight of face; face was full, rounded, and expression dull, showing distress and uneasiness. Physical examination May 19: Face full; lips, gums, mucous membrane and fauces extremely pale, almost bloodless; chest well developed, no atrophy of muscles, lungs normal; heart normal, unless slightly hypertrophied, sounds normal; slight anemic murmur; impulse not exaggerated; apex-beat in fifth intercostal space; abdominal muscles well developed; no tympanites; no distention; no retraction in epigastric region; extending into right and left hypochondriac and upper portion of umbilical regions were several small nodules, the size of an almond and plaques of two to four inches were found in the subcutaneous tissues, which appeared to be collections of adipose tissue. Several were also found on the legs, arms, forearms and back, though small and well defined. On pressure, marked tenderness was made out in epigastric region and to a less degree over abdomen; no severe pain could be evinced; region of appendix normal; stomach normal in size; spleen normal; liver normal; kidney area free from tenderness; genitals normal; reflexes not tested; sexual desire entirely lost. Patient insisted that many of his regiment suffered from the same symptoms, several of them dying; and that he had passed worms in November and December. No diagnosis was made; other treatment than bismuth, which he had used for the control of bowel movements, was deferred for the day. May 20, condition was very much the same, temperature 101.5 to 104, pulse 125, respiration 24, appetite capricious; evacuations eight. Examination of blood requested to determine possibility of malaria or ameba of tropical dysentery. Iron and arsenic were ordered, also proper dietary. May 24, condition was same; thymol ordered, two grains every two hours in emulsion on empty stomach, to be followed by castor oil. May 25, condition was much the same; temperature 101 to 103; bowels moved 20 times, large soft evacuations, but were not saved as directed. Treatment continued. May 26, condition seemed weak, thymol continued; some nausea, no appetite; temperature 101 to 104; pulse 130, respiration 24; evacuations 12, increased by oil. May 28, he was weak, sweating, distressed from thymol; dose reduced; unable to sit up; bowel movement frequent; appetite poor. May 31, as no adult worms had been found and patient had become so nauseated from thymol, ethereal extract of male fern was substituted, one to two drams a day, followed by oil; otherwise condition was not improved, weak and depressed. June 3, patient's expression was better; complains of insufficiency of liquid diet; pulse stronger, 120; temperature 101 to 102; respiration, 24; evacuations 10; treatment continued. June 5, expression was growing easier, with less distress and uneasiness; pulse 120; temperature 100.5 to 102. Color seemed better, mind clearer, desired food; felt better than for months. June 8, male fern was now given on alternate days, a dram to two drams in four doses. The bowels acted less frequently even after four and six doses of oil. The temperature showed a tendency to remain lower, highest reaching 101. June 10, bowels did not move; increased doses of oil ordered; he took 8 ounces without effect; highest temperature, 101; pulse, 104; respiration 20. June 15, pulse stronger, 96, gaining in fulness; bowels would not move without large doses of oil. Temperature had not risen above 101; respiration, 20. Eye brighter, expression much improved, tongue clearing, pallor of lips and nails improved, little tenderness over the abdomen, muscular power returning, appetite very good, general improvement marked. June 18, temperature for three days was normal in morning, 100 in evening, depending on indiscretion of diet. From this date patient showed rapid and marked improvement. Patient's weight at this time was 168 and he felt perfectly well, though the blood count did not sustain this opinion. Besides the ankylostomum the patient was also infected with the trichocephalus dispar. Since this case had been found it was reported that several cases had come to the Presidio General Hospital from the Philippines and that one case had been found at the County Hospital.

DR. H. A. L. RYFKOGEL, in connection with this case, presented the following report: On May 22, the case just reported was referred for examination of blood and feces. Examination of feces showed large numbers of the characteristic ova of ankylostomum duodenale; a few eggs of trichocephalus hominis, and

oscaris lumbricoides were also found. The stool passed after the first dose of male fern was unfortunately thrown out, and with it probably the majority of the parasites. A few eggs still remained in the feces, and in three subsequent examinations eight female worms were found. In one stool a lumbricoid was also discovered. The eggs of the ankylostomum and lumbricoid disappeared in about two weeks, but those of the trichocephalus were found in the last examination, which was in October. Examination of the blood gave the following result: Red blood cells, 2,130,000; white blood cells, 18,600; hemoglobin, 15 per cent. The differential count showed 9300 neutrophiles, 6138 eosinophiles, large mononuclear, and 2418 lymphocytes; 33 per cent. normoblasts to the cover were present. After the expulsion of the parasites, the red cells and hemoglobin rapidly rose. On July 5, the red cells numbered 3,735,000 and the hemoglobin was 28 per cent. The white cells at this time numbered 10,000; of them, 49 per cent. were eosinophiles, 2900 neutrophiles, 600 large mononuclears and 1600 lymphocytes. Seventeen days later another count was made and the red cells found practically the same; the hemoglobin had risen from 28 to 40 per cent. at this date; notwithstanding the fact that no ova of the uncinaria were found in the stool for a month the leucocytes had increased to 15,340, of which 54 per cent. were eosinophiles and 5000 neutrophiles. Eight days later the leucocytes numbered 24,500, a rise of 9000, although the patient was steadily improving. The differential count showed 14,000 eosinophiles and 5125 neutrophiles. September 21 his total white count had gone down to 13,000, eosinophiles 5148 and neutrophiles 4750. Notice was then called to the fact that although the neutrophiles varied in number they were never very high, 9000 being the result of the first examination. After the expulsion of the worm they dropped to 2900, and were again about normal, or 5000, at which they had since remained. The eosinophiles varied within wide limits, but were always much greater than the maximum normal of 800 per mm. They had dropped from 6100 to 4900 and for some unknown reason rose again to 14,200.

Rapid Healing of Tubercular Bone Cavities.

DR. S. J. HUNKIN, after referring to the metallic and earthy fillings, called attention to a rapid means of closing these cavities by the natural bone growth. The process consisted in filling the cavity after operation with carbolic acid, allowing it to remain two minutes and then follow it with alcohol and pack with alcohol gauze, removing the packing as easily as possible to prevent bleeding. Dressings were repeated every four or five days. No douche was used, the dressings were simple, easily borne, not painful, and the result was a clean wound, with no discharge at any time, and rapid closing of the cavity. This had been in from 5 to 15 dressings in a series of 10 cases. He presented several cases showing the result of this treatment.

Surgical Treatment of Ulcers.

DR. D. D. CROWLEY read this paper and offered a few suggestions. In years past he had had fair success in the treatment of ulcers by freely incising the surface of the ulcer, including the callus. During the past year he had not completely dissected away the callus but had cut the callus margin into small semilunar flaps, with narrow skin attachments and had covered a considerable part of the ulcer surface with the same, making the flap a part of the skin bordering the ulcer with one end slightly attached. An oval incison is made one-fourth to one-half inch in length, which begins at the margin of the ulcer, is carried obliquely through the calloused skin, along the outside of the callus and then gradually inwards toward the margin of the ulcer but not to the ulcer, the narrow neck of skin carrying a sufficient blood supply to the flap. The flap outlined should be next separated from its basic or sub-attachment throughout. These flaps are coaxed as far toward the center of ulcer as their skin attachments permit. The flaps bleed and turn bloodless, but nearly all retain their vitality unless conditions are very perverse. The surface is dressed with aseptic gauze which is held in place respectively by the moderate pressure of adhesive plaster and bandage. The ulcer is subsequently dressed every three or four days as conditions indicate. At the first removal of the dressings following the plastic work, there is an entire absence of callus. The flaps are slightly shrunken, though generally they adhere to the ulcer surface and exhibit signs of vitality. In several instances he had carried on this plastic work in old ulcers where very few granulations were present and in the process of repair following, the small flaps would almost disappear during the repair of the ulcer. The author described this flap work from calloused margin of ulcer because he did not know that methods used by him had been resorted to by others, or mentioned in any of the publications.

Transverse Suprapubic Division of the Skin in Performing Abdominal Sections.

DR. HENRY J. KREUTZMANN had used this form of incision in several cases and recommended it because of, 1, the better view obtained of the organs operated upon; 2, the avoidance in a large proportion of the cases of a visible scar; and 3, the almost entire prevention of a subsequent hernia.

NEW YORK ACADEMY OF MEDICINE—SECTION ON PEDIATRICS.

Stated Meeting, Nov. 14, 1901.

Dr. William L. Stowell in the Chair.

Automatic Siphon for Separating Top-Milk of Any Desired Percentage.

DR. HENRY L. COIT, Newark, exhibited a siphon, devised by Mr. Charles A. Meade, of his city, for the ready separation of the top-milk preparatory to the home modification of milk for infant feeding. After dwelling on the many difficulties met with in practice in using siphons for this purpose, he said that this was the first of many siphons that seemed to him to have satisfactorily solved the problem. The siphon is made of three-eighths of an inch glass tubing, and has a funnel-shaped extremity to the longer arm. The siphon is started by filling it through this funnel with water or milk, and then closing the other end of the siphon with the finger while inverting the instrument and placing the longer arm in the milk bottle. On removing the finger the siphon begins to draw off the lower milk, and keeps this up until the level of the milk in the bottle corresponds with the level of the outer or shorter arm of the siphon, when it ceases automatically. By attaching different lengths of glass tubing to the outer arm by means of a rubber coupling it becomes a simple matter to have the action of the siphon cease at any pre-determined level, or, in other words, to leave behind in the milk bottle the desired number of ounces of top-milk.

DR. H. D. CHAPIN said that while this seemed to be a most excellent siphon, he had long ago discarded the use of siphons because of the difficulty of getting nurse-maids to use them properly. In their stead he now used his little tin dipper, and found it simpler and more accurate.

Foreign Bodies.

DR. SARA WELT-KAKELS exhibited a safety-pin which had been removed from the vagina of a child. It had given rise to a long-continued and most obstinate leucorrhea, which had not been cured until the discovery and removal of this foreign body. She also showed a skiagraph of a child from whose esophagus she had removed a penny.

The Value of the Widal Reaction in Children.

DR. MILTON A. GERSHEL presented a carefully prepared paper on this subject, based on observations made for over three years at the Mount Sinai Hospital. He had made use of Dr. E. Libman's method of testing, and had used a dilution of one in twenty and almost always specimens of dried blood. The paper was based on the results of 670 examinations made in 199 cases. Of this number, 84 cases had typhoid and 81 of these gave the Widal reaction. In the 115 other cases of febrile disorders none gave this reaction. The Widal reaction, he said, was of special importance in children because of the frequently atypical character of typhoid in young subjects.

Primary Intestinal Tuberculosis in Children.

DR. DAVID BOVAIRD, JR., said that the percentage of tuberculosis in cattle varied in different abattoirs from 12 to 18 per cent. The tuberculin test had shown in some places from 15 to 30 per cent. The chief danger was from the milk of tuberculous cattle. Ernst had found the tubercle bacillus in 5 per cent. of 114 samples of milk taken from cows in which there were no visible tuberculous lesions of the udder. The proportion of tuberculous cattle having tubercular lesions was quite small, some authorities placing it at 3 per cent. or less. Undoubtedly the action of the digestive fluid is sufficient to protect against tubercle bacilli in milk unless these are present in large number or the digestive organs are in an unhealthy state. He had been able to find only 16 reported cases in which the relation between the development of the intestinal tuberculosis and the infection of the milk with tuberculosis had been clearly shown. A good rule for the guidance of the pathologist in determining the source of a tuberculous infection was that the oldest and most advanced lesions are found in the lymph nodes connected with the tract through which the infection entered. He had collected 236 cases from German writers, with 29 reported cases of primary tuberculosis of the intestine, or 12 per cent. Again, French writers had reported 128 cases with no instance of primary tuberculosis of the intestine. The English report 748 cases with 136 examples of primary tuberculosis of the intestine, or 18 per cent., and there are 369 cases from American writings, with only 5 cases, or 1 per cent., in which the tuberculosis was primary in the intestine. The autopsy records of the New York Foundling Hospital show 250 cases of tuberculosis in children under five years, with only 5 primary in the intestine. This represented 11 per cent. of the autopsies done in that hospital.

DR. W. H. PARK said that the finding of a primary tuberculosis in the intestine was no proof that the infection had come from tuberculous milk; it was just as likely to originate from the ingestion of human tubercle bacilli. The speaker then referred to some animal experiments done during the past summer at the laboratory of the health department. Four calves, proven by the tuberculin test to be healthy, were fed for some time on large quantities of tuberculous sputum from human beings, and a fifth calf was kept as a control. At the end of three months the four calves had all responded to the tuberculin test, but two of these animals had remained apparently in good health. One animal was now emaciating.

DR. R. G. FREEMAN remarked that animal experiments on the introduction of tubercle bacilli into the bowel had shown that the animals develop a respiratory tuberculosis, which soon becomes more marked than the intestinal tuberculosis.

DR. BOVAIRD said that cases in which animals infected through the intestine develop advanced pulmonary lesions are rare, whereas it was the rule when animals are given bovine tuberculous material for the intestine to become infected before the respiratory tract.

DENVER AND ARAPAHOE MEDICAL SOCIETY.

Regular Meeting, held Nov. 12, 1901.

Dr. H. G. Wetherill in the Chair.

Tent Life and Simplicity in Treatment of Phthisis Pulmonalis.

DR. WILLIAM K. ROBINSON said that formerly there was little difficulty in placing tuberculous patients on "ranches," but in the last few years a great dread has been inculcated in the minds of boarding-house and inn keepers so that it is now almost impossible for the invalid to secure a home in the country. This state of affairs suggested to him the necessity for establishing the Tent Colony. The plains were selected in preference to the mountains, because of the uniform temperature and other metereological conditions. The Colony is situated 30 miles from Denver; the soil is sandy; trees are in abundance. It is sufficiently far from the irrigation district to insure freedom from excessive humidity, and also from the city to escape smoke. The tents, arranged around the central building, are connected by canvassed vestibules. In the winter the beds are warmed with hot-water bottles, blankets are used instead of sheets; pajamas are made of heavy flannel with feet and hood. Patients use cheese cloths for expectorations, which are burned. Bedding is exposed to sun daily. The tents have board floors and sides 2 feet high. Bill of fare is composed of milk, eggs, vegetables and meat. They are instructed to spend most of their time exposed to the rays of the sun. They are required to bathe neck and chest with cold water every morning. Change of clothing is regulated according to weather. The ranch is supplied with current literature, games and horses.

The progress of the Colony during the last two years has been satisfactory. During the exceptionally cold weather last winter the patients slept in tents and suffered no inconvenience. Very few drugs have been used. Cod-lived oil, creosote and guaiacol have not been administered. Patients in the active stage of the disease are required to rest. It is better to err on the side of overcaution in prescribing exercise to such patients. Discussions and comparing of notes are discouraged. He recited cases that showed marked improvement, subsidence of the cough, increase in chest expansion, skin losing its paleness, catarrh and hemorrhages arrested; they become less sensitive, more hopeful, etc.

DR. HENRY SEWALL dwelt upon the great benefit derived from tent life, yet he thinks there are many disadvantages which have yet to be overcome. The tents are too hot in summer and too cold in winter. The food furnished in the ranches is in the majority of instances abominable. He is of the opinion that all cases coming under the observation of physicians should be watched for two or three months and the heart carefully and frequently examined. A heart that does not react well in a high altitude should be sent to a lower altitude.

DR. W. C. BANE related his experience of tent life in Glen Park where the system of cottage tents is in operation in which the disadvantages of canvas tents referred to by Dr. Sewall are overcome.

DR. J. A. WILDER ascribed the gratifying results of tent life and sanatoria to the fact that the patients are under the immediate control of the physician.

DR. J. CHASE said that absolute outdoor life is being practiced by thousands of healthy people in Colorado with the result that mortality among such communities is reduced to the minimum, they all enjoy rugged health, and very seldom require the aid of a physician. At one time the National Guard of Colorado camped for several months during a very cold winter, and not a case of pneumonia or bronchitis developed in their midst.

DR. WILLIAM P. MUNN said that several years ago a number of cases of smallpox in Denver could not be accommodated in the Hospital for Contagious Diseases. He had them placed in hastily constructed tents. While there were several deaths among the cases that remained in the Hospital, none died of those who lived in the tents.

Corneal Diseases Due to Smallpox.

DR. EDWARD JACKSON reported a case of a man aged 30 who came under his observation six weeks from the time he was taken with smallpox. Photophobia was intense; right eye was small; zone of pericorneal redness, gray infiltration of upper part of cornea. A few pustules extended into the infiltration. Vision equaled counting fingers at one foot, lids were hyperemic and swollen, left eye was normal. Applications of tannin and glycerin to everted lids and instillation of atrophic sulphate with bathing of the eye in very hot water, and the use of a solution of boric acid and holocain was employed. Within two days, pupil dilated fairly; eye was less sensitive. Two weeks later the vision improved to 4/60, and the eye appeared normal except for an intense haziness of the upper portion of the cornea.

A New Operating Table.

DR. T. M. HOPKINS exhibited a model of an operating table. He claims that what is commonly called surgical shock is in

many instances due to the fact that the patient remains for an hour or longer in contact with the wet and cold table, be it metal, glass or wood; that a physician in ordinary practice would never allow his patient to remain in a cold and wet bed, and that the patients undergoing an operation if conscious would strenuously object to such rough treatment. To overcome these objections he constructed a table the upper slab of which represents a tank which can be filled with hot water, the quantity and temperature being regulated by appropriate contrivances.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

PRESCRIPTION WRITING, VI.

(Continued from page 1630.)

Medicines Administered Combined and Individually.

The synergistic action of medicine must necessarily be borne in mind when one is writing a compound prescription; otherwise the results might prove disastrous to the patient. It should also be remembered that there is no organ of the body which is not subject to the action of more than one drug; a prescription may contain some constituents which act similarly to one another upon one organ and dissimilarly upon others.

In writing a simple prescription, the physician, knowing the physiologic dose and action of the drug, will meet with no difficulty; but by the combination of two or more active ingredients whose physiologic action is directed especially toward one organ, the calculation of the dose of each demands closer scrutiny.

The action of heart tonics, to illustrate more fully, may be referred to in this connection. There are many in this class, those in more common use being digitalis, strychnin, strophanthus and spartein. If the condition of the heart should demand digitalis one would ordinarily prescribe 10 to 15 minims of the tincture at a dose every four or five hours. However, if the combined action of digitalis and strychnin would better serve the purpose, the dose of each should be reduced accordingly. Such combination is commonly of great service, for the simple reason that the same effects are produced through different routes—digitalis acting upon the heart muscle directly and stimulating it, and strychnin producing the same results through the nerve supply.

Purgatives produce much better results and fewer subjective symptoms when a number of them are combined. The reason assigned is that, as different preparations act upon different parts of the intestine, the entire canal is in this way best reached. Catharsis induced by a medicine which irritates the inner lining membrane of the intestine alone is not as satisfactory as when a mild irritation of both the membrane and muscular coat is produced.

Butler gives a good illustration as to the value of the combining of remedies which act similarly upon some organs and dissimilarly upon others, as demonstrated by the effects of chloral and morphin. Chloral produces sleep by its action on the brain, and also has a distinct influence on the heart, but none on the intestinal tract. Morphin acts on the brain and has little influence on the heart, but has a powerful effect on the intestine. The two produce a combined influence on the brain, promoting sleep, with the least possible disturbance of the heart and intestinal tract.

Sometimes a remedy is required, extremely nauseating to the taste, which the patient will refuse to take; if it can be combined with a menstruum, making it a pleasant preparation, the proper results will be obtained. In prescribing for children the preparations should be made pleasant and palatable, otherwise the physician will obtain the ill-will of his patient, which is a great obstacle in the way of a successful management of the case.

The chief object of every practitioner, however, should be to prescribe as few remedies as possible and to avoid the use of any medicine, the physiologic action of which he is not familiar with. It is very desirable to administer some remedies alone. In the treatment of certain stages of syphilis, for example, potassium iodid is of great service, given in gradually increased doses until 90 to 150 drops of the saturated solution, perhaps, are given three times a day; consequently it would not be practicable or convenient to combine this with a menstruum because of the difficulty in graduating the dose. Arsenic is another drug of specific action, and in order to obtain its best physiologic effects, gradually increased doses should be given, in the form of Fowler's solution, which is of 1 per cent. strength; to administer it in any other form would make it difficult to graduate the dose in such a manner that no disturbance of the stomach would follow.

(To be continued.)

Antipyrin in Chorea.

The following combination containing antipyrin is recommended in treatment of chorea:

℞.	Sodii bromidi Potassii bromidi, āā.....3i	4
	Antipyrin .....gr. xxx	2
	Aq. menthæ pip. q. s. ad.....℥i	32

M. Sig.: One teaspoonful three or four times a day according to the age.

As a heart stimulant alternating with the above:

℞.	Tinct. adonis vernalis.....3i-3iii	4-12
	Elixiris simplicis q. s. ad.....℥i	32

M. Sig.: One teaspoonful three or four times a day, according to age.

Treatment of Chilblains.

The following is recommended in the form of a liniment:

℞.	Olei rosmarini Olei camphoratæ Sol. plumbi subacetatis, āā.....℥i	32

M. Sig.: Apply locally to the affected parts.

Morgens recommends the following:

℞.	Tinct. iodi 3ii	8
	Acidi tannici 3i	4
	Collodii 3x	40

M. Sig.: Apply locally.

In chilblains when the skin is broken, the following is recommended by the *Western Druggist:*

℞.	Zinci sozoiodol 3iiss	10
	Vaselini 3v	20
	Ceræ flavæ 3vi	24
	Olei olivæ .....℥i	32
	Terebinthinæ (Venice) .....℥i	32
	Balsami peruvianæ 3i	4

M. Sig: To be applied locally.

Frost Bite.

The following is recommended by Lassar:

℞.	Acidi carbol. 3ss	2
	Ung. plumbi 3x	40
	Lanolini 3x	40
	Olei olivæ 3v	20
	Olei lavendulæ 3ss	2

M. Sig.: As a local application.

The following, containing ichthyol, is of great service in treatment of frost bite:

℞.	Ichthyol Resorcin Acidi tannici, āā.....3iii	12
	Aq. destil. .....℥ii	64

M. Sig.: Shake and apply locally twice daily if the skin remains unbroken.

Treatment of Pertussis.

H. H. Haralson, as stated in the *Monthly Cyclopedia of Pract. Med.*, recommends for a child two years of age, two drops of the tincture of belladonna three or four times daily,

and gr. 1/150 to gr. 1/80 of heroin every four or five hours. The two remedies may be combined in one prescription, as follows:

℞. Heroin hydrochlorid. .....gr. 1/8 to 1/4 | 008-015
Tinct. belladonnæ 3ss 2
Spts. frumenti .....ʒss 16
Syr. simplicis q. s. ad.....ʒii 64
M. Sig.: One teaspoonful every five or six hours.

Treatment of Arthritic Eczema in Children.

The following is recommended by Comby as noted in *Amer. Med.*:

℞. Sodii bicarb.
Magnesiæ calcin., āā.....gr. iii | 20
Pulv. nucis vom. .....gr. 1/8 | 008
M. Ft. chartula No. 1. Sig.: One such to be taken before each meal in a teaspoonful of milk.

Local treatment should consist in the application of zinc ointment to which menthol or salicylic acid has been added in small amount. The following makes a splendid combination:

℞. Acidi borici
Zinci oxidi, āā.....gr. xxx 2
Vaselini
Adipis benzoinatis, āā.....3v 20
M. Sig.: Apply locally.

And the following as a dusting powder:

℞. Acidi salicylici .....gr. xv 1
Pulv. talci
Pulv. amyli
Lycopodii, āā 3v 20
M. Sig.: Apply locally as a dusting powder.

Treatment of Night Sweats in Tuberculosis.

J. Straussberger, in *Ther. Monats.*, states that while atropin has proven to be a powerful medicine in checking the night sweats of tuberculosis, yet its action is harmful to the digestive system of the patient. He recommends as a substitute a preparation containing formalin, viz., tannoform, as a harmless powder, which can be intrusted to the patient to apply himself; he states that it does not irritate the skin as pure formalin does and yet acts as well in checking the sweats. He prescribes it in the form of a dusting powder as follows:

℞. Tannoform .....ʒss 16
Pulv. amyli .....ʒiss 48
M. Sig.: Apply locally by means of a pad of cotton-wool.

Medicolegal.

Expressions Showing Expectancy of Death.—The Supreme Court of Florida holds, in Clemmons vs. State, 30 Southern Reporter 699, that any expressions of one mortally wounded at the time of making an alleged dying declaration, tending to show that he then believed his death was imminent, are admissible in evidence for the purpose of determining whether the declaration then made was in fact a dying declaration. The dying declarations of a deceased person relating to what was said by him or the accused, and what happened between them at the time of the fatal encounter, it holds, are properly admissible in prosecutions for unlawful homicide.

City Not Liable for Detention of Smallpox Suspects.—The Supreme Court of North Carolina says that it must be admitted that the party suing in the case of Levin vs. the City of Burlington received heroic treatment, and was damaged. According to his allegations, he was a peddler by occupation, and stopped one night at a boarding house in the city, leaving the city in the morning. A police officer followed him some nine miles, and arrested him on a warrant from the mayor. He was taken back to the city and compelled to stay for twenty-one days in the house he had lodged in overnight, because a case of smallpox had been discovered in the house, although he protested that he had not been exposed to the disease, and even offered for his own quarantine elsewhere. Besides, he alleged that he had been forced to undergo vaccination twice during his confinement, and alleged loss in his goods and injury to his horse from its use and bad treatment by the authorities. But, notwithstanding all this, the Supreme Court of North Carolina holds that he had no cause of action for damages against the city. It says that if he was arrested and detained by the officers of the law, under the process of the law, and for the purpose of enforcing the law, he had no right of action, unless he could show malice or improper conduct on the part of the officers in its execution. Then his right of action would be against the party or parties maliciously instituting the proceedings, or the officers for improper conduct in making the arrest and detention. Again, it says that, in this case, the officers seemed to have been acting under the statute, and that it is settled in that state that a municipal corporation can not be held liable for the enforcement of a public law for the public good.

Test of Responsibility for Crime, Defense Insanity.—In the murder case of the State of Maine vs. Knight it was earnestly contended by counsel that an uncontrollable insane impulse to commit a criminal act might co-exist with full knowledge of the wrongfulness of the act, and that the legal test of responsibility for crime afforded by the knowledge of right or wrong, respecting the act committed, had proved to be insufficient and unsatisfactory. It was accordingly insisted that the time had arrived when this criterion of responsibility could be safely modified by incorporating into the rule the element of irresistible impulse. To this the Supreme Judicial Court of Maine replies that it is undoubtedly true that in the progressive development of the medical jurisprudence of insanity more enlightened views have gradually prevailed respecting the functional activity of the mind, and the course of symptoms indicating mental disease, and that just conclusions have more frequently been reached by courts and juries in recent years in regard to the relation of insanity to criminal responsibility. But since the announcement of the decision of this court in State vs. Lawrence, 57 Me. 574, in the year 1870, this abstruse and difficult question has been the subject of exhaustive re-examination and renewed study, in the light of all modern discoveries of scientific truth bearing upon it by the most eminent medical and legal jurists in this country and England, and by courts of the highest authority in both countries; and it is still held by an overwhelming weight of judicial authority that, when the insanity of the accused is pleaded in defense, the test of his responsibility for crime afforded by his capacity to understand the nature and quality of the act he was doing, and his mental power to distinguish between right and wrong with respect to that particular act at the time he committed it, is the only proper legal criterion; and that, when fully developed and explained to the jury, in its application to the special facts and circumstances of different cases, it will always be found adequate to meet the demands of justice and humanity toward the accused, as well as to insure the protection and safety of the public. So, this court still adheres to the old rule, approved in the case above mentioned. It further says that it is evident that much of the diversity of opinion or difference in modes of expression upon this subject arises from a failure to discriminate between that irresistible impulse produced by an insane delusion or mental disease which had progressed to the extent of dethroning the reason and judgment and destroying the power of the accused to distinguish between right and wrong as to the act committed, and that uncontrollable impulse which is alleged to arise from mental disease, and to coexist with the capacity to comprehend the nature and wrongfulness of the act, but which may, with equal reason and consistency, be attributable to moral depravity and criminal perversity.

Medical Attendance for Employes—On Injured Miners.—The Supreme Court of Montana says, in the case of Spelman vs. the Gold Coin Mining and Milling Company, that the implication of a promise, one the part of one who requests the performance of medical or surgical services for another, to pay for them, does not arise unless the relation of the person making the request to the patient is such as raises a legal obligation on his part to call in a physician and pay for the services.

To make him liable, there must be an express promise or engagement to pay by the one who called in the surgeon or by his authorized agent. This is also true with regard to corporations. In this case, certain employes of the mining company were injured by the explosion of a blast, while working in its mine, and, so far as appeared, without its being in anywise at fault. One of them was the assistant manager and foreman. Being taken with the others to a hospital, he told the surgeon that the company would pay all the expenses incident to their treatment. The general manager also promised that it would pay all expenses for their treatment. But the court holds that the company was not thereby rendered liable. It does not think that the general manager had any implied authority, under the circumstances, to bind the company by employing physicians and surgeons. Besides, it says that while there can be no doubt of the implied power of a corporation of the class to which this one belonged to incur expense on account of injuries received by its employes in the line of their employment, in the absence of any express statutory grant of such power, the law unquestionably is that such a corporation does not owe to its employes any implied legal duty to do so. It would not seriously be asserted that a natural person owes to his servant or employe the legal duty to furnish medical or surgical aid to him, or to nurse him when sick or disabled, or when injured while working for the master or employer. Indeed, the court apprehends the law does not impose such obligation upon him in any event without an agreement by which he assumes such burden. For instance, a servant suffers a bodily injury through the actionable negligence of the master; although the master must answer to the servant in damages for all loss proximately resulting, including physicians' and surgeons' charges, yet the law does not require him to engage their services, or to pay them for performing the services. He may, if he chooses, employ physicians, surgeons and nurses, and promise to pay them, and, of course, he would then be liable directly to those employed. Whether or not, in such a case as the one last suggested, the general manager of a mining company can bind his principal, the court says it was not necessary to decide on this appeal, because, as has been said, there was nothing to indicate that the company was at fault, or that it had agreed with the wounded men to provide surgeons or physicians for them in case of accident. If the directors had met and employed them to attend the men, they would have bound the company; but the directors would not thereby have performed a duty imposed by law upon them or upon the company. Beyond doubt, also, the corporation, through its board of directors—its governing body—possessed the right at any time to delegate the exercise of this power to any officer or person.

AMERICAN.

1. **Vaccination.**—Crandall gives a historic résumé of the effects of vaccination, showing how variola has been nearly stamped out in Prussia by the operation. He sums up the lessons taught from experience in the following: "1. The first lesson can not be better stated than in the words of the Berlin Board of Health: 'Vaccination in infancy, renewed at the end of childhood, renders an individual practically as safe from death from smallpox as if that disease had been survived in childhood, and almost as safe from attack.' 2. The duration of the immunity conferred by vaccination is variable. In many individuals vaccination in infancy, and revaccination in childhood is sufficient for life protection. In a limited number, immunity is lost in five or six years. It is never possible to know with certainty to which class an individual belongs. In the face of an epidemic, therefore, vaccination of all who have not been vaccinated within five or six years, is giving what the lawyers call the benefit of a reasonable doubt. Every one who has been vaccinated in infancy and childhood, should be vaccinated not less than once in adult life. 3. The immunity conferred by vaccination is in direct proportion to the thoroughness with which it is performed, and this is shown with considerable accuracy by the character and number of the resulting scars. 4. Vaccination in infancy alone is not sufficient to wholly prevent smallpox among the adult population. 5. Optional vaccination has not proved sufficient to protect the community from smallpox. Compulsory vaccination is a measure warranted by more than a century of experience. 6. The mild compulsion enforced in this country, by requiring vaccination or evidence of its recent performance upon admission to the public schools, should have the hearty support of parents and physicians alike."

3. **Tetanus in Vaccination.**—The Camden epidemic is the basis for Willson's paper and he disagrees with the circular sent out by the Camden Board of Health, especially in their statement that tetanus does not develop later than eight to ten days after infection. He reports a case and while he admits that in all the cases of tetanus it must be acknowledged that the incubation period was greatly prolonged, he still thinks that the statement made is incorrect. In his case the child's father was a coachman and another similar one is referred to. He believes the tetanus bacilli were carried from the stable to the child either by the father or someone else and he does not think that the chronic or delayed form has ever shown such a mortality as has occurred in this tetanus epidemic in Camden, N. J. Therefore, he holds that the cause in the several cases was probably subsequent to the original vaccination. The cases point to neglect on the part of physicians, not in the vaccination itself, but in properly watching the cases afterwards. The occurrence of tetanus should not influence careful persons against the only safeguard against smallpox, but should arouse the medical profession and the laity to studying the proceeding and adopting measures that will ensure the proper execution of the vaccination and subsequent supervision of the vaccine sore.

4. **Vaccine Production.**—Groff suggests the appointment of a commission, preferably by the American Medical Association, to investigate and report upon the following points: 1. From what tissue or pathologic product in the vaccinated animal should the virus be taken, and at what time after vaccination. 2. What is a typical vaccine vesicle, stating accurately the appearance on different days, and what is a typical vaccine scar. 3. Means of positive diagnosis of the "mild form of smallpox in which there are no deaths." He has come to the conclusion that when a smallpox epidemic is present the virus supplied physicians is much more attenuated than is the case when such epidemic does not exist. He notes the methods of preparation of different firms and says that in the 800,000 vaccinations made in Porto Rico by the military government under his direction with virus produced on the ground, neither the scab, the lymph from the sore, nor the granulating tissue under the scab were used; only the product containing the virus.

6. **Gastric Massage.**—In the conclusion of Knapp's paper he holds that the effect of gastric massage is more psychical than otherwise and would recommend it simply for its psychic effect. Whatever good there is in massage the stomach is not adapted for it.

7. **Gaertner's Tonometer.**—The tonometer is of use according to Crummer in the following conditions: In diagnosis by eliciting the tension in cases in which the mean blood pressure is symptomatically changed; in prophylaxis in keeping tract of the blood pressure where we desire to have the earliest possible knowledge of lack of compensation found in valvular lesions and in kidney diseases; in prognosis in acute cases, in judging the maintenance of the power of the heart, read directly by means of the instrument; therapeutically as a measure of the effect of drugs or other treatment given for the production of changes of arterial tension.

10.—See abstract in THE JOURNAL of October 19, p. 1058.

11. **Hypodermoclysis.**—Hollopeter has been employing hypodermoclysis in some of the ailments of early life and finds it of great value in specially selected cases. His technique is given as follows: In afebrile cases, such as are found in general atrophy, wasting following infectious disease, etc., the solution should be at least 115 to 120 degrees and delivered to the tissues at 106. This temperature must be kept up throughout the procedure. The injection may be made either by a large hypodermic syringe or by gravity if suitable apparatus is obtainable, but this is slow. He thinks in very young children the old-fashioned large antitoxin syringe holding one to two ounces, after being thoroughly sterilized by boiling, is filled with normal saline solution of the proper temperature, which is injected into the flank or into the inner surface of the thigh above the knee, or preferably near the great trochanter, on the outer aspect of the lower extremities, this being the area of least sensibility and is also free from pressure when the child is lying down. It may be necessary to benumb the skin by the application of pieces of ice for a few minutes or a little atomization with sulphuric ether. It is never necessary to introduce the fluid with a large syringe so rapidly as to produce swelling. When the tissues are wasted or starved by loss of blood they will drink up the fluid much more rapidly than when the body is full of fluid and toxins. Several cases are reported and he says in conclusion that the method offers a very wide field of clinical usefulness. The appearance of a surgical procedure may frighten young children or the family, but in spite of this, he finds it an unusually powerful remedy that has given him far better results than any simple procedure ever

tried. To recapitulate, its chief fields of usefulness are in hemorrhage in the newborn, from the genitals or umbilical cord; in purpura; in cases of general wasting from intestinal disturbances; and especially the toxemias associated with the acute eruptive fevers, scarlet fever and diphtheria claiming an especially high degree of usefulness. In syphilis and in tuberculosis it is a therapeutic measure which aids very materially the uses of other means to effect restoration.

13. **Sterility in the Male.**—Blech reports a case where, probably following specific urethritis, there was a condition of sterility accompanied with a few dead spermatozoa in the semen which was cured, contrary to his expectations, by the use of negative galvanic applications to the prostatic urethra, 5 to 12 milliamperes, lasting 5 to 8 minutes. The indifferent pole was placed on the back. He does not attempt to explain this cure after 11 years' diseased condition and blames himself for not having examined or properly treated the urethra in the case.

14. **Borderland Conditions.**—The special borderland conditions between medicine and surgery noticed by Woolsey are carcinoma of the stomach and appendicitis. In regard to the latter he believes in early operation, as diminishing the unnecessary element of mortality. Improvement is needed, he thinks, in medical practice in the line of early diagnosis, especially in the cases of malignant new growths and septic processes. The responsibility rests with the physician to not only make an early diagnosis but to call in the surgeon to apply appropriate treatment.

16. **The Psychic Half.**—Gilbert's article is a protest against the materialistic methods of thought and expression in medical and other literature. Medicine is not justified, he says, in looking at the cases entirely on the physical side. Experimental psychology has promised much more than she has fulfilled or ever can fulfill. He specially criticises the attempt to define consciousness by physical terms, explaining the psychic realities by chemical and other theories.

17. **Bronchostenosis.**—After describing the symptomatology of bronchial spasms Abrams maintains that many cases of bronchitis are merely cases of bronchial spasm which can only be relieved by climatic change, and he emphasizes particularly the value of iodid of potash in this condition. In his experience it is a specific, though it must be given with circumspection. The medium daily dose is about 30 gr., though 60 is not excessive when no idiosyncrasy is shown. We must specially guard against iodism; individuals with defective renal apparatus are especially liable to this. The promotion of diuresis by drinking largely of water or milk may obviate iodism. Belladonna in the form of tincture, 5 drops with each dose of iodid of potassium, will prevent the objectionable coryza. If digestive disturbances occur Fowler's solution may be given and Briquet suggests bicarbonate of sodium, and sulphanilic acid has been given for a similar purpose. He offers the following formula as of value in certain cases of bronchostenosis:

℞. Iodid of potassium 3 5
Tincture of lobelia 3 10
Spirits of glonoin (1 per cent.).....m. 16
Elixir bromid of potassium q. s. ad.....℥ 4

M. A teaspoonful three times a day after meals. This dose may be gradually increased if necessary.

20. **Stab-Wound of the Heart.**—Vaughan reports a case of stab-wound of the heart sutured some one-half to three-quarters of an hour after reception. The patient died of hemorrhage which was free with each pulsation through the wound. He analyzes the cases that have been reported, including some 26, in which there were 9 recoveries. It appears the ventricles are much more likely to be wounded than the auricles and the left ventricle most frequently. His conclusions are that the time has arrived when a wound of the heart should be operated on with as little hesitation as a wound of the brain, with the expectation of, under proper conditions, getting good results. The mortality will necessarily be high, not from the operation but from the injury, especially if all cases, including desperate ones, be undertaken. Cases that have survived five or more hours after receiving the wound will give a good percentage of recoveries, but such selection is not to be recommended. 2. In all cases of wounds in the region of the heart, with symptoms threatening life, an exploratory operation should be done by making an osteoplastic flap by dividing the fourth and fifth costal cartilages at their attachment to the sternum and ribs, about one inch external to their attachment to the cartilage, somewhat according to the method of Roberts. This flap turned up as a door on a hinge gives a good view of the pericardium and can easily be enlarged upward if more room is required. 3. While early and speedy operation is often essential to success, yet the importance of asepsis can not be too strongly emphasized on account of the great danger of pericarditis and empyema. If there has been much hemorrhage an amount of physiologic salt solution, approximately equal to the blood lost, should be injected into the vein while the surgeon is operating, if it has not been done before.

22. **Bilocular Stomach.**—Cumston's long article contains two cases in detail and covers the whole subject of bilocular stomach. No operation, he says, can be decided on before the abdomen has been opened and the condition therein ascertained. When the surgeon has become perfectly familiar with the anatomical condition present he may select the operation most applicable, which, taking all things into consideration, is usually gastro-anastomosis according to Doyen's and Woelffer's methods. It is, he believes, indicated in all cases of bilocular stomach, especially when the stenosis is long and narrow and where cicatricial atrophy of the cardiac pouch has occurred and there are a large number of adhesions. It is more rapidly performed than resection, and it is a more perfect operation because it re-establishes stomachic digestion in its entirety.

23. **Tuberculosis.**—Baldwin reports cases of tuberculosis of the hypophysis, of the intercostal tissues near the sternum with secondary tuberculosis of the axillary lymph glands, primary tuberculosis of the Fallopian tube with large tubercular veins in the ovary, tuberculosis of the thyroid, tuberculosis of the uvula and a case of tubercular adenomatous polyp of the cervix.

25. **Ulceromembranous Angina.**—Although this condition was previously recognized by French and Russian authors it has only been noticed within the last three years by Germans. Sobel and Herrman describe the localization, which is usually on the tonsil, most frequently on the right, the ulceration varying in size from that of the nail of the little finger to the involvement of the greater part of the tonsil, irregularly circular or oval and chancroidal in character. The depth varies from one-eighth to half an inch, and sometimes extends throughout the gland. In all the 12 cases examined there was some elevation of rectal temperature, in 4 ranging up to 101 and 103. With two exceptions the submaxillary glands were enlarged on the same side as the lesion and usually remained so for some time after the healing of the ulceration. The symptoms were usually entirely local, the fever rarely being high enough to produce constitutional symptoms. Clinically it differs from diphtheria in that it has an ulcerative process instead of a membranous. From confluent follicular amygdalitis it is distinguished by the absence or mildness of constitutional symptoms. The bacteriology of the condition is discussed at length and the organisms found described. The authors consider that the fusiform bacillus of Vincent is probably the special microbe of the condition on account of its uniform presence in such large numbers or in nearly pure culture, and the gradual disappearance during the process of healing, and its rapid destruction when the ulceration heals; the rarity of other micro-organisms and the fact that in some cases it seems to be transmissible. The prognosis is invariably good, a cure usually occurring within three weeks. The majority of cases were locally treated with silver nitrate, 3 to 5 per cent. In two instances Lugol's solution was used with apparently good results. Brief histories of the cases accompany the paper, with a bibliography.

26. **Appendicitis.**—Deaver maintains that every death from appendicitis is preventable, excepting, of course, the fulminating type, if the operation is performed in due season. The symptoms are not characteristic singly, but the diagnosis should be made by anyone from the three cardinal symptoms, pain, tenderness and rigidity. He maintains that it is unjustifiable to defer operation in any case after the diagnosis has been made. The condition of walled-off abscess is a most unfortunate state of affairs and not a favorable outcome of conservative treatment as is sometimes held.

29. **Nephropexy.**—The new principle announced by Beck consists in suspending the kidney, after having button-holed it on the fibers of the nearest muscle. He briefly reports a case. The principle of the method is similar to that of his modified method of ligamentopexis illustrated in the *American Journal of Obstetrics*, Vol. xlii, No. 8, 1900.

31. **Hernia Epigastrica.**—In the conclusion of his article Lothrop discusses the etiology, pathology, anatomy and symptoms of the condition. It may be due to embryonic defect, to weakness in the abdominal walls and to trauma, and there is evidence of the influence of properitoneal fat and terminal vessels and nerves in its causation. The fatty tumors and epigastric hernia are usually of slow origin and tend to develop at the point where the vessels pass forward through the anterior sheath of the rectus muscle, particularly in the linea alba. The steps of this process are given in the remarks on pathologic anatomy. It is quite possible that these elements may give rise to no disturbance whatever, but in the common type there is more or less gastro-intestinal disturbance with or without local pain. It is a good rule to examine the epigastrium in gastric disturbance to make sure as to this condition. The symptoms referred to the stomach may be nausea, vomiting, increased acidity, eructations and occasionally palpitation where the heart's action becomes embarrassed. The motile power of the stomach may be interfered with. Pain is commonly present. All of these symptoms usually follow a meal, sometimes in proportion to the amount of the ingesta. Tenderness may be present or absent in any case, and in some cases in fat patients the tumor may be difficult to be palpated. Tumors in the region of the epigastrium should suggest this possibility. The prognosis is not bad in cases where there are no symptoms, though it may give rise to symptoms at any time. If it causes any trouble treatment is indicated. Operation, however, is the only means of relief when symptoms are troublesome and it is very important to free the omentum from all adhesions, and recurrence is unusual.

33. **Abdominal Contusions.**—Bottomley has analyzed some 40 cases of abdominal contusions, equal numbers with and without severe intestinal injury, causing severe intestinal trouble, and analyzes symptoms. Pain was present in all the more severe cases, and is the most constant symptom and of no special diagnostic value. It was present in all but one of the simplest and mildest cases. Vomiting occurred both in the mild and severe cases. It was absent in 2 cases of intestinal injury and in 7 cases of simple contusions, and was not mentioned in 8 cases of the former and 3 of the latter class. Shock appeared as an intestinal symptom in 10 cases of intestinal injury and 7 of contusions of the abdominal wall. Muscular spasm was present at entrance in 11 of the intestinal injuries and 10 of simple contusions; it was absent in 2 of the more severe and 4 of the less severe injuries. Other symptoms were distension, tenderness, which is one of the most constant signs, external signs of violence which are not always present; dulness was present in the minority, and variations of the temperature, pulse, etc. Nothing definite was obtained from a study of these special symptoms. Of the 20 cases of injury of the intestine 19 died and 1 recovered; 11 were operated on and 9 treated expectantly. Of the latter all died. In simple contusions of the abdomen, the symptoms disappeared in an average of 4.4 days and the cases were discharged in 8 to 15 days. The general result of the study was that the physical signs respond neither to the amount of violence nor to the amount of injury done, and we have no means of distinguishing between simple abdominal contusions and one complicated by severe injury except by exploratory incision, and this to be of value must be done in a very short time, three to five hours after the injury.

34. **Vaginal Section.**—Reynolds and Friedman have, in their recent practice, abandoned the abdominal method of extirpation of infected tubes and other collections of pus in the abdomen and confined themselves to thorough drainage by the vagina without attempting the removal of the affected viscus, excluding, of course, cases of twisted pedicle, etc. The method of operating consisted in using a wide cut across the posterior fornix and frequently supplemented by continuing the incision in the median line, thus making a T-shaped cut. The first incision only penetrates the vaginal walls, but is always extended on the sides out to the pelvic walls and posteriorly as far as may be necessary; the flaps are dissected back and a similar incision is carried through each succeeding layer until the abscess mass is itself plainly in view; its wall is incised and the incision extended with scissors, or the fingers, until it is as wide as the original incision in the vaginal vault. All edematous inflammatory tissue is torn open with the fingers as far as possible and the cavity then lightly packed without douching. There is usually free venous hemorrhage, but this is due to back pressure on the veins and will cease as soon as the mass is reduced by the escape of its contents. They divide these sections into two classes: 1. Those in which a definite abscess cavity containing liquid pus (a pus-tube or encysted peritonitis) was isolated by a more or less heavy wall of inflammatory exudate. In this class the risk of general peritonitis is greatly diminished by this operation. Excellent drainage may be secured, severe post-operative shock is almost unknown, and vaginal hernia is a rare sequence. In the second class characterized by infiltration and subsequent degeneration of the cellular tissue of the pelvic septa, vaginal section gave no immediate and obvious results, but the result of section was a rapid drop in the temperature and pulse with marked symptomatic relief.

44.—See abstract in THE JOURNAL of November 30, p. 1481.

45. **Intestinal Surgery.**—Benjamin concludes that close approximation of the opposing surfaces preventing leakage and peritonitis can be best secured by the use of the Murphy button or the Czerny-Lembert or the Halsted sutures. Maintenance of the lumen, especially in the small intestine, is best secured by the Murphy button. However, where sutures are alone used and are carefully introduced, not allowing puckering to take place at the time, nor turning in too much, a small opening does not follow, as shown by his experiments. Adhesions around the exposed raw surfaces are best avoided by the use of the elastic ligature, though there is little chance of this occurring in Maunsell's operation. Where too many sutures are introduced there may be gangrene from cutting off of the blood supply. This is avoided by the Murphy button, and especially by the elastic ligature. The contents of the bowel are best prevented from infecting the wound by the use of the Murphy clamp or a tie of gauze around the intestine. Traumatism is avoided by using sutures of elastic ligature, but often caused by using the Murphy button. In the matter of time the Murphy button and elastic ligature take the lead. Of sutures the Halsted, which does not penetrate the mucosa and leaves less suture material exposed, is followed by fewer adhesions and makes a close approximation. When used by Connell's method still fewer adhesions result. Cushing's continuous suture is also very satisfactory. The square knot is the most suitable, and should be only firm enough to approximate the membrane. The continuous suture, apparently excepting Cushing's, is not very safe. It is likely to slough out in places unless anchored frequently by a half stitch. When the sutures penetrate the mucosa and are tied on the serous membrane, a peritonitis or infection by capillarity sometimes results. Care should be observed in putting in the mesenteric stitch and all stitches on the concave side of the bowel, to avoid cutting off the blood supply. The external row of sutures or an excess of stitching often causes gangrene. Na-

ture saves many cases by supplying an extra barrier to infection by the omentum plastering itself around the place of danger. This is well to remember as the omentum can easily be stitched around the questionable point.

46. **Gastro-Intestinal Surgery.**—Cutts describes and illustrates McGraw's plan of using the elastic rubber ligature for anastomosis. The technique is as follows: Hold the intestine firmly between thumb and finger; introduce a darning needle into the intestinal wall into the lumen of the bowel, passing the needle on for an inch and a half, again penetrating the wall of the intestine, and bringing the end of the needle out. While an assistant holds the bowel, make traction on both ends of the rubber ligature so as to make it as small as possible, and then draw the needle and ligature through the intestine at the desired amount. Now grasping the other loop of the intestine to be united, pass the needle and ligature through it likewise, but in a reverse direction; then tie a single knot in the rubber ligature, over which have the assistant tie a fine knot to prevent the slipping of the knot. Repeat the knot in the rubber ligature; likewise the silk thread to hold it. The loops of the intestine within the grasp of the ligature are thus greatly folded and massed together, but they straighten out and become perfectly smooth, leaving an opening between the intestinal walls varying in size with the amount of bowel included.

52. **Accidents.**—Adams gives the classification of accident insurance companies as to risks, which is of interest to physicians. Workers in nitroglycerin, soldiers in barracks or field service, professional baseball players, submarine divers, aeronauts, circus riders, and U. S. deputies supervising moonshine districts are excluded absolutely. Brakemen on freight trains, couplers, miners, and trimmers of electric light carbons are limited to $250 in case of death for which they must pay the premium of $30. Next comes the "specially hazardous" class, in which the insured must pay $25 per year and be limited to $1000 in case of death. Among these are cowboys, cattle-tenders, buzzsawyers, hunters, lumbermen, sawmill employes, and employes of furniture and sash, blind and door manufacturers running machinery. The next class is the "extra hazardous," who are compelled to pay $20 and be limited to $1500 in the average insurance company. Among these are railway engineers, firemen, conductors, bridge-builders and bridge-carpenters, sailors, well-diggers, wood-choppers, and employes in iron and steel manufactures. Next come the hazardous occupations who pay at the rate of $15 for $1000, and are generally limited to $1500. It is rather surprising that the farmer and farm laborer are included in this as well as the common laborer, dairymen, coal-heavers, icemen, telegraph linemen, quarrymen and cornice-setters. The blacksmith, butcher, carpenter, professional fisherman, and sea pilot are also included and the captains and mates on vessels. The extra-medium class which pays $12.50 yearly, limited to $1500, includes the bartender, cable and electric road employes, celluloid workers, distillery employes, volunteer city firemen, employes in glass factories and hostlers. Coming down to the ordinary risks entitled "medium," limited to $2000 at the rate of $10 per thousand, it includes most ordinary businesses, as house-painters, boat-builders, book-binders, bottlers, cabinet-makers, chocolate-makers, ferrymen, makers of agricultural implements, makers of bicycles and attendants on the insane. It also includes certain railroad employes, such as car-painters, car-cleaners, airbrake inspectors, truckmen at the stations, etc. It also includes the men who travel habitually on the Pullman cars, such as cooks in dining cars, hotel cars, porters and Pullman conductors who are considered to be less exposed to accident than the ordinary trainmen. The next division is that of the "extraordinary," where the amount is limited to $2000 at the rate of $8.50 per thousand and is rather an exclusive one, and contains such occupations as superintendent of furniture manufactures, who, while not actually running the machines, directs and makes repairs. The "ordinary risks" include such businesses as bartenders in first-class hotels, billposters, bookbinders, boiler inspectors, superintendents of buildings and a large number of trades. The "extra preferred" need pay only $6 per thousand and insure up to $5000, including general superintendents, supervising contractors, supervising proprietors, or manufacturers in the various lines of business. Insurance companies regard the men who supervise the work of their employes personally as not as good risks as if they confine themselves simply to office work. The next two classes, the preferred and the select, pay only $5 and $4 per $1000, and include persons employed in office work, ministers, typewriters, etc. Physicians are better risks than surgeons, and the city physician is better than his brother in the country. The city physician is put in the first class, the select, then the physician and surgeon with city practice only, while the country doctor and surgeon is put down on the ordinary, which is fourth from the top, for which he pays twice as much as his city brother, and is limited to half the amount of indemnity in case of accident or death from accident. This is the cold-blooded view which the accident companies take of the dangers of the country doctor's life.

57.—See abstract in THE JOURNAL of September 28, p. 849.

59.—**Tuberculous Peritonitis in Childhood.**—Cotton is dubious as to the necessity of surgical interference in tuberculous peritonitis in children and holds it probable that similar hygienic conditions to the usual post-operative ones might have an equally good effect. Put the affected part at rest as far as compatible with good nutrition. Give concentrated liquid diet to diminish peristalsis, keep the patient in the recumbent position to prevent diffusion of peritonitis and to economize energy. Abundant supply of fresh air and the maintenance of body heat are essential. The stools should be kept liquid without exciting undue peristalsis. Ascitic fluid should be evacuated as frequently as found necessary, and the abdomen, if large, should be supported by a bandage. The well-known action of creosote, guaiacol and iodin upon tuberculosis and the fact that these are eliminated by all the secretions, their presence in ascitic fluids having been demonstrated, suggests a promising field for their exhibition. Iodoform 10 per cent. with lanolin may be applied over the abdomen daily, and its internal administration is claimed to be beneficial. Cod-liver oil should not be forgotten. Protonuclein has found favor with some and should be theoretically indicated. In support of his view he reports a case thus treated, the only surgical operation being aspiration of the abdomen, and asks: If the apparent cure is real, has the improvement been influenced by therapy and would a laparotomy have produced any better results?

60. **Intestinal Exclusion.**—Beck maintains that side-tracking a portion of the bowel is the best method to obtain a palliative cure in an otherwise intractable intestinal fistula or inoperable tumor and may be employed with perfect safety to the patient. He says he speaks with some authority since he had the rare opportunity of performing 8 laparotomies on one individual before he was cured of his intestinal fistula and he gives the case in detail. He also gives other cases illustrating his views and concludes that total exclusion of a portion of the bowel offers excellent means in curing otherwise intractable conditions.

70.—Ibid.

71.—Ibid.

72.—Ibid.

73. **Pancreas in Diabetes.**—After first reviewing the literature as regards the specific changes in the Islands of Langerhans in diabetes in the papers of Scobolew, Opie, Weichselbaum and Stangel, Herzog reports the results of his examinations of the pancreas in four cases of diabetes. In only one was the examination sufficiently thorough to warrant conclusions, but the result was well in accord with the observations of previous writers. In all four cases there was a certain

marked increase of connective tissue and thickening of the capsule of these bodies. In one case only a few of them were found with difficulty.

82. **Vaginal Section.**—After mentioning the methods adopted by Orthmann, Mackenrodt and others, Webster describes his own practice. He makes a circular incision of the cervix just below the attachment of the vaginal wall. This is joined by a mesial incision an inch and a half or more in length, dividing the anterior vaginal wall. The cervix being well pulled down, the wall of the vaginal vault is stripped upwards until the anterior peritoneal pouch is reached. The anterior wall is also stripped somewhat from the base of the bladder. The utero-vesical pouch is then opened. The advantages he claims for this method are that the uterus can be pulled down to a greater extent and that more room is obtained for intra-pelvic manipulations. The latter may be sometimes facilitated by a transverse incision through the pouch of Douglas. Occasionally with enlarged uterus or chronic metritis it is advisable to ligature one or both uterine arteries which are easily exposed in the raw surfaces made. When the enlarged uterus can not well be brought down its descent can be assisted if the base of one or both broad ligaments are divided internal to the ligatures. At the end of the operation the uterus is pushed into place and the peritoneum closed and the original vaginal incision closed with chromic catgut. He describes the adaption of this method to cervical amputation and anterior colpotomy.

87.—See abstract in THE JOURNAL, xxxvi, p. 756.

90.—Ibid., p. 908.

95. **Embolism of the Central Retinal Arteries.**—The cases reported by Würdemann were deep massaged according to Casey Wood's method and the fortunate results are believed by the writer to be mainly due to dislodgment of the blood clot by means of the renewed blood supply. Starvation of the nerve cells of the retina was absolutely complete in the first case and but partial in the second; the return of the visual function in the former complete and in the latter incomplete. He does not think the drug treatment given at the same time should be credited with the cure.

96. **Optic Atrophy.**—After first reporting his case, Barrett reviews the others in the literature and speculates as to the origin. He is inclined to believe from all the evidence that the explanation will be found in a combination of vascular factors, operating on a terminal arterial system, altered blood, disturbed nutrition of vessels, spasm, and possibly thrombosis of the artery or vein.

100. **Alaskan Diseases.**—Kelsey reports his medical observations in Alaska at St. Michael Island and Andraeofsky, respectively. He finds there occurring a severe form of cerebrospinal meningitis, but the chief scourge of the country is scurvy. Typhoid fever also occurs under proper conditions. Rheumatism is neuralgic in type; the inflammatory type is never seen excepting in the summer time. Pneumonia does not occur there during the cold weather; when it does occur in the spring and summer in the damp and warm weather it is more or less afebrile in type. Neuralgias are frequent like other nervous diseases such as neuritis, spastic paraplegias, etc. Alcoholism is frequent. Insanity is often seen. Gastro-intestinal complaints, especially gastritis, constipation, intestinal indigestion and diarrhea due to improper food are mentioned. Among the natives cerebrospinal meningitis and scurvy do not occur, but chronic bronchitis, consumption, pneumonia in the rainy season, smallpox, measles, syphilis, la grippe, etc., are especially severe.

101. **Cardiac Inhibition.**—Curtin reports a case presenting certain peculiar phenomena, especially the murmur which he considers is congenital. Its point of occurrence was neither on the aortic or mitral area and the blood did not pass through the tricuspid orifice with sufficient force to produce murmur. The circulation was at no time impaired and no preceding disease likely to cause endocardial trouble appeared to have existed.

113. **Descemetitis.**—The existence of descemetitis as a special condition is combated by Bruns, who reviews the literature and reports cases. His conclusions are: 1. That there can not be any such disease as serous iritis; it is equally impossible to conceive of a serous cyclitis or choroiditis. "Simple" cyclitis would seem to be a term of evasion. 2. Descemetitis, on which the diagnosis of serous iritis was long made to rest, is a symptom sometimes appearing as an accompaniment of a focus of acute inflammation in the iris, ciliary body, or choroid. 3. It may also appear in cases of uveal disease so slight and evanescent that we are unable to determine the location of the focus, and here the term incipient uveitis more correctly indicates the diagnosis. 4. Descemetitis appears also in certain cases of subacute or chronic uveitis, where the focus can not be determined, but an inability to find it does not justify the diagnosis of simple subacute or chronic cyclitis. 5. Further observation will probably show it to be frequently the principal symptom of an acute plastic choroiditis which has been overlooked because too few cases of iritis or cyclitis are subjected to careful ophthalmoscopic examination after recovery and the complete disappearance of the vitreous opacities. 6. Many cases not to be clinically distinguished from such acute plastic choroiditis show to the ophthalmoscope after clearing of the vitreous no evidence of lesion in the choroid. In this it is reasonable to suppose that the choroidal focus was so peripheral as to be out of the field of observation. 7. Plastic choroiditis often appears under the clinical picture of the so-called serous iritis, but such cases usually are observed after a stage of circumcorneal injection and descemetitis has passed away.

114. **Lachrymal Endothelioma.**—The new growths of the lachrymal glands are discussed with special reference to the occurrence of endothelioma, by Warthin, who sums up his conclusions in the following: "1. The great majority of the lachrymal tumors described in literature under widely differing heads are most probably mixed tumors of endothelial origin similar in structure to those of the parotid and submaxillary glands. These tumors form a type peculiar to the serous glands and differ from the endotheliomata found in other parts of the body in their tendency to form cartilage, hyaline, and myxomatous tissue, and in their relatively slight malignancy. 2. Histogenetically they arise from the flattened endothelium of the lymph-spaces, and hence are called endotheliomata, but their peculiar characteristics warrant the employment of some special designation. The use of the term endotheliomata in itself appears somewhat misleading in view of the fact that endotheliomata elsewhere are of the nature of sarcoma and are for the greater part very malignant. These growths partake more of the nature of mature connective-tissue tumors. The designations, myxochondroma endotheliale, chondroma endotheliale, etc., might be employed as the case warranted to indicate both histogenesis and structural characteristics of the growth in the absence of any specific term for the cells lining the tissue-spaces or the tumors derived from them."

115. **Anisometropia.**—From the cases here presented Duane offers the following conclusions: "1. In the large majority of cases of anisometropia, even those in which the difference in refraction exceeds 2 D., the full correction can be applied with success, provided the patient is warned that it may take him one or two weeks to get accustomed to the glasses, and that during this period he must use them steadily. 2. In many instances temporary discomfort is produced by the glasses, but in the majority of such cases the discomfort soon disappears, if the glasses are steadily worn. The period of time that it takes a patient to get used to the glasses so that they no longer give discomfort, varies from a few hours to one or, it may be, two weeks. 3. After the patient has become accustomed to the glasses, they are not only worn with ease and satisfaction, but also often relieve important symptoms, which glasses not compensating the anisometropia do not relieve. 4. It is especially important to apply the correction when there is a beginning squint, which is evidently due to the anisometropia. Yet it is in these very cases that

we may expect difficulty in the acceptance of the glasses. 5. The causes of temporary or permanent discomfort in using glasses are: (*a*) either the strength of the glasses per se; (*b*) the unequal prismatic action of the unequally strong glasses; this gives rise either to diplopia and confused sight, or to muscular asthenopia due to efforts made in overcoming the prism; (*c*) the presence of a muscular deviation producing diplopia. The glasses in this case, by enhancing the distinctness of the double images, force them more upon the patient's attention, so that they are more difficult to ignore, and hence give more trouble than when seen without the glasses. This I believe to be one of the most frequent causes of a permanent difficulty in using the glasses. 6. The statement that glasses correcting the anisometropia cause trouble by producing retinal images that are of a different size in the right eye and in the left is probably fallacious, trouble not being caused in this way. 7. In anisometropia there is a moderate tendency for the right eye to be the more refractive of the two. In my cases, the right eye was the more refractive in 58 per cent. and, counting only the cases of high anisometropia, was the more refractive in 64 per cent. 8. In anisometropia the proportion of cases in which the right eye is the more ametropic about equals those in which the left eye is the more ametropic. 9. Anisometropia is very frequently conjoined with muscular anomalies, and particularly (in 41 per cent. of my cases) with divergence (exophoria or divergent squint). The divergence may be due either to a convergence insufficiency, or to a divergence excess, the latter condition being comparatively common. In the cases that I examined, convergent deviations were less than half as frequent as the divergent. 10. In anisometropia of low degree there is no special tendency to the development of hyperphoria. In high anisometropia hyperphoria is unduly frequent (occurring twice as often as in low anisometropia). 11. The proportion of cases with squint (especially divergent squint) is high, convergent squint being found in 11 per cent., and divergent squint in 14 per cent. of my cases."

116. **Torticollis.**—Dallwig reports two cases of torticollis dependent upon a vertical deviation of one eye and the attempt of the patient to overcome the visual disturbance by holding the head obliquely. In neither of his cases did he operate, but in one the ocular condition and the lateral separation of images have decreased and the obliquity with which the head is held has diminished.

119. See abstract in THE JOURNAL of September 28, p. 852.

132. **The Framework of the Human Spleen.**—The summary of Kyes' conclusions is as follows: "1. Within the lobule of the human spleen there is a delicate network of fibrils continuous throughout the pulp cords and the Malpighian follicles. 2. The fibrils of this entire network are reticulum in the sense of Mall. 3. The fibrils encircling the capillary veins are an integral part of this reticulum network and are not elastic tissue. 4. The so-called specific elastic tissue stains yield a positive reaction with reticulum as well as with elastic fibers."

134. **Hemolymph Glands.**—Warthin describes the hemolymph glands in the human subject, comparing them with those found in certain of the lower animals. He thinks that a study of these broadens our conception of the lymphoid tissue, and he gives a comparative table of the lymph organisms. In regard to the relations between the blood and lymphatic systems the red marrow might be considered the most primitive type of lymphoid structure, and the ordinary lymphatic glands the most developed, the hemolymph glands and spleen occupying intermediate positions.

139. **Retained Testicle.**—This condition is apparently, in Bartlett's opinion, most probably due to a mal-development of the organ. In the three cases reported there was more or less absolute or relative connective tissue increase besides mal-development of the glandular element. The disadvantages to the individual are serious as these organs in their abnormal condition are liable to be the seat of tumor formations and frequently malignant disease. If treated sufficiently before complete maturity an effort must be made to bring down one gland at least, as has been done by Casati and Boyer and others, or spontaneous descent must be favored by a proper transposition of the tissues as Sargi and Trombetta have proposed. If nothing is done until after maturity removal of the organ will do no harm.

141. **Right-Sided Anatomical Tripod.**—This comprises the common symptoms of gallstone, kidney stone and appendicitis, and Thomas points out the chief distinctions, calling particular attention to the following: 1. Relative to the three distinct locations in which the pain begins. 2. That except a reactionary temperature be observed, no elevation is expected at the beginning of the attack except in appendicitis. 3. The tenderness on pressure corresponding with the different locations of the trouble. 4. The different character of vomit. Most of the other symptoms outlined are sufficiently characteristic and not found in all the conditions discussed.

143. **Modern Surgery.**—The requirements of modern surgery, according to Carstens, are: "1. A patient brought to the highest state of resistance to microbic infection and made as clean as possible. 2. An operating room, preferably in a hospital, where everything has been made thoroughly sterile. This includes anesthetizer, assistants and nurse. 3. A surgeon who has a mechanical hand and has received a thorough and long training."

147. **Asthenopia.**—Tennent goes over rather briefly the general conditions of asthenopia, convalescence, and weakness, and offers the following conclusions: "1. General disease is the aggravating cause in a large proportion of asthenopic cases. 2. Grave diseases, notably typhoid and tuberculosis, give rise to retinal exhaustion and other severe symptoms. 3. Retinal exhaustion is usually found with other neurasthenic symptoms and improves under patient treatment."

FOREIGN.

British Medical Journal, November 30.

A Case of Syphilitic Arterial Disease. WILLIAM R. GOWERS.—Gowers reports a case in a woman aged 25, who had suffered from headache, mental distress, vomiting, loss of power on right side and had had some kind of fit. It was thought she had had syphilis; she was ill-nourished and anemic and unable to account for herself. There was considerable right hemiplegia, weakness of the right side of the face, complete paralysis of the upper arm, but she could move the forearm and hand a little; power of the leg was limited to slight movement of the foot. There was also foot-clonus and impaired sensation; the left side was normal; the discs were also normal. Mercurial inunctions were ordered, followed by some improvement, which soon ceased and potassium iodid treatment was begun, 15 grains per day. She died on the 26th day after admission with sudden paralysis of the left side, having gradually failed most of the period. The postmortem examination revealed a syphilitic arteritis, most intense at the commencement of each middle cerebral artery where the passage of the anterior cerebral from the inner carotid converts the latter into the middle cerebral, diseased growths having entirely surrounded the vessel. In each middle cerebral the disease was continued for about one-half to three-quarters of an inch and spots of disease beyond. The left anterior cerebral was smaller than the other and pale, and the right middle cerebral was occupied by a recent clot, extending from its origin throughout the vessel. This must have been the cause of the final hemiplegia. The left middle cerebral was completely closed and contained an old clot occupying the vessel for about a third of an inch. Beyond this thrombus the artery contained fluid blood. The circulation had been maintained in the distal portion by aberrant arteries from the posterior cerebral joining the middle cerebral just before its division, which had prevented the extension of the clot. Another abnormal vessel, a duplicate communicating one of the circle of Willis, kept up the circulation in the anterior cerebral. The occurrence of the limited clot in the left middle cerebral must have caused the onset of hemiplegia. The clot in the anterior cerebral may be assumed

to have caused the onset of the mental symptoms. The cause of the progressive increase of symptoms was the change in the brain substance due to endarteritis of the terminal arterioles showing increasing effect of the diminished blood supply. The severe persistent headache was the result of morbid processes in the vessels which made the symptoms otherwise also simulate those of tumor. Death in this case was inevitable, but the diagnosis of the actual condition during life was impossible. Gowers thinks that while we can not repair the vessels damaged in the way they were, we should give iodids, but not in such large doses as are sometimes given, as it is possible that there may be some truth in the theory that iodids favor the coagulation of the blood. The dose given the patient, 15 grains three times a day, was ample to influence such disease and as much as is wise to give, and the possibility of getting accustomed to the drug should be considered. It is possible that morbid processes might be such as to acclimate the patient to iodids in spite of them. He insists on care that is necessary and desirable in giving the prognosis of cases of such disease of the cerebral arteries and the value of the scientific imagination in many such diagnoses.

Some Cases Illustrating the Necessity for Accurate Observation in the Management of Surgical Cases. WILLIAM H. BENNETT.—The unreliability of pathogenic symptoms is the motive of Bennett's article. We should dismiss from our minds the possibility of single symptoms being evidence of any disease. He illustrates this fact by several cases: one diagnosed strangulated hernia which turned out to be a case of very early extrauterine pregnancy, one of perimetritis which had been operated on for hernial tumor which was not the cause of the trouble. Two other cases are reported showing the danger of depending too much on any one symptom: one of strangulated hernia which gave free impulse on coughing, and another of abdominal contusion with absence of liver dulness due entirely to the wearing of a tight strap or belt, the patient being a laborer. Attention to details in surgical diseases is especially emphasized and the constant appeal to exploratory operations deprecated.

The Lancet, November 30.

The Symptoms and Treatment of Movable Kidney. HENRY MORRIS.—The author first defines movable kidney, describing the varieties, giving those in which it can be readily found and those in which the kidney moves in a "cinder-sifting" manner behind the peritoneum, where the organ slides, so to speak, upon the plane of the posterior parietes, never "dropping" forwards or inwards, and so not properly described by the term nephroptosis. It also sometimes rotates more or less around the vertical and transverse axes. The reasons why opinions as to the frequency of this condition vary, are given by him as due to superficial examinations, the different ideas of movable kidney, some claiming that it is abnormally mobile whenever it is at all felt by palpation during deep inspiration and the fact that physicians at health resorts whose patients are mostly dyspeptic and who systematically employ methods of palpation undoubtedly find larger numbers than those that only treat patients under ordinary conditions. He describes his method of detecting movable kidney, the patient being in the recumbent position, by bimanual palpation and also describes Glenard's and Israel's methods. The symptoms are described; they may be negative, but they also may be serious in certain cases. The most common effect of movable kidney is general impairment of health, with languor, debility, loss of flesh, vertigo, constipation, hypochondriasis, and various neurotic states. The most frequent effect on the kidney is hydronephrosis, either intermittent or persistent. As regards treatment he has little faith in trusses or bandages; while they may keep the kidney in place they do not fix it in its proper place and require to be continuously worn, often to great discomfort. He attaches no value to rest in the recumbent position. His conclusions as to treatment are as follows: "1. When movable kidney is associated with enteroptosis, no operation should be performed on the kidney unless it is evident that the more serious symptoms are due to the movable kidney alone, and not until after the trial of a well-fitting abdominal support and the careful dietetic and medicinal treatment of the gastric and intestinal disorders. Should these means fail and the kidney be evidently most at fault, nephropexy, followed by the wearing of an abdominal belt, should be tried. 2. When a movable kidney is complicated by a movable liver, or when both kidneys move, the same rule should be followed as in general enteroptosis; in the case of both kidneys moving (when both organs have been giving trouble) they should be fixed one after the other at an interval of a week, so that convalescence from both operations may be taking place simultaneously. I have in several instances thus operated on both organs with the most satisfactory results. 3. When the movable kidney occurs in a hysteric or neurasthenic patient, all palliative means should be tried before resorting to an operation, and the patient's friends should be informed of the uncertainty of the result from the operation. The statistics show that a cure may be hoped for by nephropexy in about half of these cases. 4. For uncomplicated movable or floating kidney, in which the principal symptoms are pain and gastro-intestinal troubles, the operation may be confidently advised and carried out without any previous trial of belts or of rest. 5. When renal crises are a feature of the case, nephropexy ought to be strongly urged because of the impossibility of keeping the kidney in its proper place by a belt, and because of the constant risk of hydronephrosis and recurring pain, even if the renal crises can be kept under control. 6. When a movable kidney gives rise to no inconvenience an operation ought not to be thought of and a belt need not be worn.

Twenty-Five Years' Experience of Urinary Surgery in England. G. BUCKSTON BROWNE.—In his third lecture Browne deals with the subject of stricture. The management of this condition has made great advances and the class he here specially considers is that which can not be readily kept open by the easy and periodical introduction of the bougie. There is constant danger in this condition and he even goes farther than Syme, claiming that there is no case where the instrument can not be passed. The treatment which he believes has come to stay in these cases is internal urethrotomy in all strictures which do not yield to dilatation. Puncture of the bladder in cases of retention is justifiable in naval, military and country practice, but hospital surgeons do not have to be reduced to this necessity. In difficult stricture he maintains that filiform bougies are really dangerous, may break in the bladder and give trouble. He has no confidence in any instruments in these cases except the steel ones. The surgeon in any case should take a convenient time and be deliberate. The instruments required are steel sounds, varying from the No. 2 to No. 17. He uses the No. 7 to No. 16, a little smaller at the point than in the shaft, some blunt-ended English gum bougies from No. 3 to No. 10, a foot rule marked by inches and a No. 11 or No. 12 soft gum catheter, mounted on a stylet for tying in at the close of the operation. The patient is carefully prepared; the limbs are not exposed, but protected against the cold; when the patient is completely anesthetized, the blunt-ended soft bougie is introduced and the exact distance of the stricture carefully ascertained. Then a steel sound well warmed in vaselin should be passed, with the finger in the rectum used to guide it in the middle line. No force must be used, but a steady search made for the orifice of the stricture, and firm but steady pressure be applied when it is found. When the sound is fairly grasped no attempt should be made to pass the instrument, which is one of the smallest, unless it goes forward easily, but it should be withdrawn and the next largest applied and so on. Whence once the No. 6 or No. 7 sound has been fairly passed into the bladder, the surgeon stands on the patient's right side, draws out the sound and slips in the urethrotome. When the bulb is fairly in the bladder the experienced surgeon feels a sensation of looseness and freedom quite characteristic; to be sure that everything is right, when it is in a proper position the instrument is carefully withdrawn until the bulb is one inch from where the stricture is known to begin.

The anesthetist is warned that the patient must be kept perfectly still; the blade is then protruded and a free incision made from behind forwards for a good inch along the floor of the urethra and about half an inch deep. The blade is then sheathed and the instrument withdrawn. A full-sized sound is then passed, No. 12 or No. 13; if it goes in easily, a larger one is also used. Then the soft catheter, mounted on a stylet curved so as to exactly correspond with the curve of the sound, is passed in and the stylet removed, and the catheter is tied in. The urine escaping will show that all is right and if there is any doubt it should be withdrawn and again passed in. On no account should any water be injected through it until there is no doubt that it is fairly in the bladder. When the catheter is tied in, the operation is through. He always tries to have the patient bear with the catheter at least two days. The patient sits up about the eighth day and with the periodic passage of two or three well-warmed and well-oiled steel sounds, the largest usually No. 14 (English), the case is finished. The patient can learn to use these himself. He has had experience with the operation for twenty-seven years and never lost a patient from it. The avoidance of primary manipulation is important and the operation is an excellent one even in many cases where there is no real difficulty in traversing the stricture with instruments, for example, where time is an object, when the stricture is at the urethral orifice or in the penile urethra and in cases where the gentlest interference is followed by rigor and prostration. It is also required where the stricture rapidly recontracts, when the deposit around it is large and dense and when calculus is impacted beyond it, or there is any urethral fistula behind it, and in cases of prostatic hypertrophy where the catheter has to be employed. Although he delays incising the perineum there are four conditions where this is to be advised: 1. Where there is urinary extravasation. 2. Where there is pus requiring an exit. 3. In some cases of prostatic calculi. 4. In some rare cases of urethral calculus. In all cases of periprostatic abscess and of perineal abscess, a free perineal incision must be made at once. He thinks that if the surgeon is prompt in dividing the urethral stricture a true perineal abscess never will communicate with the urethra and the patient will be saved all the trouble of urinary fistula. He does not favor opening the urethra from the outside. It is very difficult sometimes to heal up the incision, and a urethro-perineal fistula is a bad thing. He would consider opening of the urethra in vesical calculus, urethral stricture, perineal abscess and extravasation in peritoneal tissue, or vesical exploration or drainage, as a surgical mistake.

Alkaptonuria. ARCHIBALD E. GARROD.—According to Garrod this urinary abnormality seems to have some connection with consanguinity of parents, and he brings forward certain facts showing the frequency of its occurrence in children of first cousins. This supports the view that alkaptonuria is what may be described as a "freak" of metabolism, a chemical abnormality more or less analogous to structural malformations. There is no evidence of heredity, for there has never been any case of it observed as occurring in two generations. He is able to furnish facts as to the exact appearance of its onset in congenital cases, having had a patient under observation where it occurred the day after birth. He gives observations and tables bearing on the question as to the relation and time of output of homogentisic acid to a proteid meal, which did not bear out Mittelbach's observation of the reducing power of urine showing the maximum excretion two or three hours after the proteid meal, but showed that although such meal is quickly followed by a much increased excretion of homogentisic acid a still larger amount is excreted during the second period of four hours than during the four hours immediately following the meal. In other words, they tend to support the view that the change from tyrosin to homogentisic acid takes place in the tissues after the absorption of the former, rather than the alternative view that the change in question is brought about in the alimentary canal.

"Myxasthenia," With Remarks on Kindred Affections. WALKER OVEREND.—Overend suggests the term myxasthenia for a condition of special dryness and irritability of the mucous membrane. He discusses the condition showing the pathologic states with which it seems to occur, such as certain gastric and bowel troubles, bronchitis, etc., and its relation to gouty and diabetic diatheses.

Annales des Mal. Gen. Urin. (Paris), October.

Successful Perineal Prostatectomy. DEFFIS.—Macias and Gonzalez of Mexico have been treating hypertrophied prostate by perineal prostatectomy for the last ten years. Their experience now includes thirty cases. They incise the raphe of the perineum for 4 or 5 cm. and cut a buttonhole in the urethra, through which they insert an Otis urethrotome into the bladder, withdrawing it open, to dilate the urethra. The lobes of the prostate are then detached in turn with the fingers and taken out with forceps. There is very little hemorrhage. A large, flexible sound is next inserted in the bladder which is rinsed with a 1 to 1000 solution of silver nitrate. The cavity left after the removal of the prostate is packed with iodoform gauze. The permanent sound is changed the second day but is not removed for eight to fifteen days. It is then introduced through the urethra or used intermittently. The bladder is left in complete repose owing to the extensive drainage through the perineum. One patient died from an intercurrent disease and one soon after the operation from progressive debility. The others are all in the best of health so far as the urinary apparatus is concerned. As the prostate is removed from beneath the capsule—from within outward—the operation is simple and causes only slight trauma. The large vessels are all outside the capsule. A portion of the prostate is left above, which keeps the upper wall of the urethra intact, and obviates the danger of a stricture later. There has been no incontinence of urine in any case.

Hematuria of Pregnancy. U. CHIAVENTONE.—Toxemia from insufficiency of liver and kidneys is probably the essential cause of the hematuria which appears in pregnancy, with no hereditary nor personal antecedents, and terminates with the pregnancy. Congestion may be an associated factor. Ordinary measures are ineffectual against this form of hematuria. Only seven such cases are on record and Chiaventone adds an eighth. If the severity of the hematuria requires active intervention, the bag of waters might be punctured to relieve the compression on the ureters and vessels. Premature delivery might be required in certain cases.

Bulletin de l'Academie de Med. de Belgique (Brussels), July 27.

Vascular Lesions in General Paralysis. A. MAHAIN.—An infiltration of the sheaths of the smaller vessels of the cortical layer of the frontal lobe was noted constantly in seventeen cases of progressive paralysis, while it was never found in twenty-two cases of other mental affections with the exception of cerebral syphilis. In the latter no difference could be detected even with the microscope between these lesions in progressive paralysis and in cerebral syphilis.

Revue Gen. d'Ophthalmologie (Paris), October 31.

Dangers From Ligature of the Carotids. SIEGRIST.—Analyzing the 997 cases of ligature of the carotids which Siegrist was able to collect in the literature of the last century, he found that the mortality was 40 to 44 per cent. and that the operation was followed by disturbances in the eye of the same side, in 4.2 per cent. He is convinced, however, that the visual troubles were due to complications of the operation and that the mere interruption of the circulation in the territory of the carotids does not endanger the eye. He has had occasion personally to observe two cases of blindness in the eye on the same side after ligature of a carotid. In the first the internal carotid was ligated during an operation for the removal of a cancer of the base of the tongue. Hemorrhage occurring eight days later rendered it necessary to throw a ligature around the common and the internal carotid. The patient exhibited slight cerebral symptoms the same evening and the next day he found that the eye on that side was blind,

with signs of embolism of the central artery of the retina. The patient died a week later from paralysis of the heart. The autopsy disclosed embolism of the central artery of the retina from the debris of a thrombus which had formed in the external carotid, ligated eight days before. This debris had become detached at the time the common carotid was ligated, and had been swept into the trunk of the arteria centralis retinæ. In the second case, the diagnosis could not be verified by the autopsy, but the facts observed after ligature of the internal and external carotids, undertaken for the purpose of curing a pulsatile exophthalmos, also indicated thrombosis of the arteria centralis retinæ. The mortality in 172 cases collected between 1881 and 1897, was only 20.3 per cent. This number includes 113 cases of ligature of the carotid as a curative measure for pulsatile exophthalmos, with 10 deaths. Excluding the patients who died in consequence of post-operative infection, the figures show 5 deaths attributable to the ligature in 108 operations, that is, a mortality of 4.6 per cent. Siegrist concludes from his comparative study of the data that the age of the patient has no influence on the prognosis, up to 60 or even 70 years, unless he is debilitated from some cause. The prognosis is less favorable at any age when the general condition is poor as in case of malignant tumors, or considerable hemorrhage or vascular lesions, aneurysms, etc. Certain circumstances, such as some cardiac defect or the accidental inclusion of the pneumogastric or sympathetic in the ligature, render ligature of the carotid extremely dangerous in young or old subjects. Before attempting to ligate the artery the heart should be accustomed to the change in the circulation by systematic compression of the artery for some time beforehand, which will also aid in developing a collateral circulation. Infection of the wound may entail septic crumbling of the thrombus with possibly septic, metastatic softening of the brain, cerebral abscess, panophthalmitis and meningitis, not to mention the threatening secondary hemorrhages at the point of the ligature. The artery should be ligated under local anesthesia in order not to interfere with the strength of the heart-action by chloroform anesthesia, as the success of the operation depends on the co-operation of the heart. The operation is contra-indicated, unless under exceptionally urgent conditions, in case of heart disease, valvular defect, anemia or cachexia, especially if the patient is over 40. Digitalis should be administered in such cases before or, at least, immediately after the intervention. In case of post-operative dangerous symptoms, a heart tonic should be given and the heart relieved by venesection, to which the surgeons of old attributed their success in averting the dangers of ligature of the carotid. Full details of Siegrist's cases have been published in *Graefe's Archiv*, L, p. 511.

Beitraege z. Klin. Chirurgie (Tuebingen), August.

Neurofibromatosis. C. Adrian.—The progressive character of neurofibromata distinguishes them from nevi which in other respects they resemble. Neurofibromatosis evidently develops on a congenital foundation and is thus a malformation in the widest sense of the word. It is congenital or develops in youth, and its hereditary character is evident. Among the twelve cases described, three occurred in five children in two inter-related families. It is generally benign, but has a tendency to malignancy.

A Cystadenoma of the Thyroid Gland. F. Smoler.—The peculiarity of the case described was that it was successfully operated again and again and was under observation for twenty-seven years. No recurrence has been noted since the papillary cystadenoma was partially removed for the third time. In the 5 similar cases on record, the survival was only three to five years. No metastasis of this kind of tumor has ever been known. The case described is the only one that perforated through the skin.

Osteoma of the Nasal Cavities. E. Haas.—Among the symptoms of an osteoma of the nasal cavities are itching, hemorrhage, ozena and complications in the lachrymal passages. One case of spontaneous expulsion of the osteoma has been observed. It had induced suppuration and necrosis in the adjacent tissues. Haas has witnessed one case and has been able to find twenty in the literature.

Prostatopexy for Hypertrophied Prostate. E. Goldmann.—An enlarged prostate offering a mechanical obstacle to the flow of urine, is best treated by fastening the bladder to the anterior abdominal wall. The abdomen is incised on the median line, and the anterior wall of the bladder, where it is free from peritoneum, is sutured as high as possible to the abdominal wall. By this means the orifice of the urethra is made to gape without danger of infection. The autopsy of a patient who had been treated in this way but died from progressive myocarditis, demonstrated that the operation had been a perfect success in every way.

Circular Resection of Rectal Strictures. M. Reber.—Two cases of inaccessible stricture of the upper third of the rectum were extirpated after removal of the coccyx and a portion of the sacrum, and a longitudinal incision in the posterior wall of the rectum. The stricture was then removed without opening the peritoneum, and the edges of the longitudinal incision were sutured together horizontally in order to widen the lumen of the intestine.

Berliner Klin. Wochenschrift, November 4.

Improved Colpoceliotomy. A. Duehrssen.—Entering the abdominal cavity through the anterior wall of the vagina is the route long advocated by Duehrssen, who claims that it affords such ample access that the internal genitalia can be photographed with ease. It is possible, by incising the vesico-uterine pouch as extensively as possible, to ablate by this route an ovarian tumor completely filling the abdominal cavity and not projecting into the small pelvis. The tumor can be opened and the contents evacuated, after which the empty shell can easily be drawn down and extirpated. He describes a typical case of this kind, the patient a frail woman of 63, the tumor three times as large as a man's head. She was dismissed cured in two weeks and a week later took a long journey. In order to facilitate still more this vaginal operation, he has lately modified his technique to include the severing of the broad ligament, and the remarkably satisfactory results attained in the ten cases in which he has applied it, have convinced him that by this means it is possible to enter the abdominal cavity with the maximum operating space and the minimum of disturbance. By severing the broad ligament and detaching the uterus from the vagina it is possible to draw the uterus out through the vagina, where it can be inspected at ease without disturbing the appendages or its attachments on the other side. The cut shows the uterus drawn out and laid over on the vulva on one side, while the diseased appendages are drawn out in the same way. The stumps left after the ablation are fastened outside of the peritoneum before being replaced. The cicatrix left after this operation is trifling. The patients recuperate rapidly. The facilities for arresting hemorrhage are far superior to other methods. It would be possible to suture a rupture in the uterus, even in advanced pregnancy, by this method. The adhesions are exclusively sero-serous and stretch readily, not interfering with pregnancy later. If the genitalia are found too much altered to be retained, the radical extirpation is already half accomplished.

Treatment of Gonorrhea. Prowe.—The principles on which Prowe treats gonorrhea were established by observation that infection occurred almost exclusively from women with copious and irritating discharges. He considers their suppression much more important in respect to contagion than the presence or absence of gonococci. He first curettes, then applies aluminum acetate to the cervical canal and in case of proctitis, injects a 2 to 10 per cent. solution of ichthyol. He swabs the urethra with a 2 to 10 per cent. solution of silver nitrate on a cotton-tipped probe. He has been exceptionally successful in preventing contagion by this method of treatment.

Centralblatt f. Bakteriologie (Jena), October 23.

New Hypothesis of Biochemical Antagonism. R. Emmerich and O. Loew.—As a possible explanation of the mechanism of the biologic serum test of specific albumins,

serums, etc., Emmerich and Loew suggest that possibly certain racemic, that is, optically inactive substances, are split into two optic antipodes during the process. For instance, if a levulo-rotatory albumin is used for the injections, it becomes transformed in the organism into a dextro-rotatory, and the precipitation is the result of the formation of a racemic albumin by the combination of the two antipodes. The combination of a dextro- and a levulo-rotatory calcium tartrate causes a precipitate to be thrown down. This phenomenon is naturally more pronounced with the large molecules of the proteins than with the comparatively small molecules hitherto studied in this connection.

Agglutination in Various Infections. S. J. Goldberg.—The most interesting point in the extensive experimental researches reported is that an increase in the agglutinating properties of the blood should be regarded as an early sign of the successful auto-defence of the organism.

Centralblatt f. Kinderheilkunde (Leipsic), June and July.

Acute Mummifying Cutaneous Gangrene. C. Hochsinger.—A large patch of gangrene, which resembled a rubber dress-shield in size and location, developed under the arm of a healthy babe about a week old. The child died the fourteenth day. Only two similar cases are on record. One was published by Stoffregen of St. Louis. No postmortem was allowed in this case, but it is possible that a thrombus might have existed in the long thoracic artery. The axillary artery was intact and the radial pulse was perceptible.

Pemphigus in the Newborn. C. Hochsinger.—When pemphigus develops on a reddened skin in the newborn it has proved malignant, in Hochsinger's experience, while it runs a mild course if it develops on apparently normal skin. He describes one case of each kind. The lack of scab formation differentiates the genuine, infantile contagious pemphigus from contagious impetigo which it otherwise resembles. The latter has also been observed in newborn infants. The babe with malignant pemphigus died in eleven days. The mother contracted the pemphigus in each case.

Multiple Cavernous Angiomatosis. C. Hochsinger.—Only six cases of this affection have been described in the literature according to Hochsinger, and none even remotely approximated the personal case he reports. The child was a vigorous three weeks' babe. When first seen the upper layers of the cutis contained forty to fifty round or oval venous blood sacs, the size of a lentil seed. Eighty could be counted by the end of the third month, but all spontaneously vanished before the child was a year old.

Deutsche Archiv f. Klin. Med. (Leipsic), lxxi, 1 to 3.

Pavlov's Experiences with Dogs Repeated on Man. Schuele.—Pavlov found that dogs secreted gastric juice at the mere sight of appetizing food. Schuele has been repeating his tests on the human subject, siphoning out the stomach contents at various times during the day. He found that this psychic secretion of gastric juice, Pavlov's "appetit saft," does not occur in man. Human beings are trained from childhood to repress greediness, and Schuele found it impossible to induce this psychic secretion at the sight of tempting food. He found on the other hand that the glands in the stomach are stimulated to secretion by reflex action from the food in the mouth, by the purely chemical action of certain substances, by their agreeable taste and lastly, by the action of mastication alone, even when articles were masticated which were not swallowed. His tests also demonstrated that it was impossible to elicit the secretion of gastric juice by mechanical irritation of the stomach walls with the sound or other instrument, similar to Pavlov's experiences with dogs.

Deutsche Med. Wochenschrift (Leipsic), November 28.

Agglutination of Tubercle Bacilli as a New Standard for Treating Tuberculosis. R. Koch.—Efforts to protect man, to immunize him against tuberculosis have been conducted for years, Koch remarks, but they were rendered peculiarly difficult by the lack of a standard to determine what had been accomplished in the line of immunization. He has now simplified the agglutinating test for the tubercle bacilli and announces that it is possible to apply this test as a standard to estimate the actual progress accomplished in immunization. All the former uncertainty has been banished at one stroke, he states. He first established on animals the technique for the administration of the bacilli to obtain the agglutinating reaction as rapidly and intensely as possible. He then applied the results to man, and now reports 74 patients treated according to these principles, with more or less success in all but 9 cases. Four of these were evidently old, healed lesions and the others did not complete the course of treatment. He assumes that the protecting substances in the organism increase parallel with the agglutinating reaction, as pronounced clinical improvement invariably accompanies it. The appetite returned, the patients gained in weight, the night-sweats usually vanished and the expectoration decreased. Most of the patients were in the second or third stage of the disease. The agglutinating reaction was more readily induced in the early stages of the disease and could more easily be kept at a high point. In 14 patients the agglutinating power was brought to 1 to 25; 1 to 50 in 28; 1 to 150 in 6; and 1 to 200, 250 or 300 in 3 patients. Tests on 30 persons without, and 78 with tuberculosis showed that the agglutinating reaction occurred spontaneously in a number of subjects in each group, showing that it has no value for early diagnosis of the disease. Patients in the advanced stages do not exhibit the agglutinating reaction, which confirms Koch's assumption that it is directly connected with the presence of the protective substance in the organism. We know that tuberculosis is not a disease that confers future immunity like smallpox, etc., from the accumulation of the protective substance. There is not enough of the protective substance elaborated in the course of tuberculosis to induce a spontaneous cure and subsequent immunity. But Koch is convinced that this immunization can be artificially accomplished by repeated subcutaneous injections of small amounts of tubercle bacilli dust, controlling the effects on the organism by the agglutinating property acquired by the serum. One part of finely pulverized tubercle bacilli is mixed with 100 parts water and 100 parts glycerin. After standing a few days the fluid is poured off the sediment. One c.c. represents 5 mg. of the pulverized bacilli. It is diluted with .8 per cent. salt solution. A reaction is seldom observed after a first injection of 2.5 mg. The dose is then rapidly increased, repeating the injections every one or two days until a pronounced reaction is obtained, raising the temperature two or three degrees. After such a reaction the injections are suspended for six or eight days, and repeated again as needed to keep the agglutinating power at about the same high point. He injected as much as 20 to 30 mg. in several cases. This is the limit, as larger amounts are not absorbed. After the dose reaches 10 to 20 mg. the intervals between injections average from two to four weeks. In some cases the agglutinating property diminished in spite of the large doses, but he kept it at the desired point by substituting intravenous for subcutaneous injections, reducing the dose. The effect of this method of immunizing patients is most striking in regard to the temperature. Non-febrile patients never exhibited fever after the reaction which could be ascribed to the injection, and in febrile subjects the temperature was favorably influenced by the reaction. At first the temperature dropped only transiently, from the third to the fourth day after the injection; it then remained low for a few days and then gradually began to rise again. If a vigorous reaction was then induced by an injection, the temperature dropped again and lower and more permanently than after the previous injections. By continuing the injections with their reactions it was possible to keep the temperature permanently reduced. In a few cases even high fever of a pronounced hectic type was completely banished by this means. Febrile conditions, therefore, do not contra-indicate this treatment, as in case of tuberculin. Koch excluded only patients with enfeebled heart-action or extreme debility or such extensive destruction of lung tissue that improvement was absolutely impossible. He applied the treatment indiscriminately to all others, and abandoned it only in the few cases in which the weight continued

to decrease, and no agglutinating reaction could be induced. He judges from his present experience that the patients require six months or more of this treatment. After large doses have been reached and the reactions have become less violent, the patients return at intervals of two to four weeks for an injection. They should be continued until the tubercle bacilli have entirely disappeared from the sputum. This immunizing method of treating tuberculosis does not conflict with other methods. He believes that its chief sphere of usefulness will be in the advanced cases, especially for application in sanitariums after other measures have failed. He prepares the bacilli for agglutination by grinding them to a powder with caustic soda in the proportion of 0.2 of the culture to 20 c.c. of the fluid. It is neutralized to a weakly alkaline reaction with diluted hydrochloric acid and diluted with 0.5 carbolic acid and 0.85 per cent. salt solution. The final proportion is 1 part of this preparation to 100 parts of the carbolized salt solution. It is then centrifugalized and diluted with the same fluid to 1 to 1000. It can then be kept on ice for two weeks ready for use.

Muenchener Med. Wochenschrift, November 19.

Influence of Alcoholic Enemata on the Gastric Secretions. R. Spiro.—An hour after an evacuating rectal injection, 7 to 10 c.c. of alcohol in 200 c.c. of salt solution were injected. An hour later the contents of the stomach were siphoned out at half-hour intervals. This procedure was repeated every one or two days until five to eight tests had been made on the various subjects. The results demonstrated that this administration of alcohol or of a fluid containing 7 to 10 per cent. of alcohol, had a marked influence in promoting the secretion of gastric juice, the maximum occurring one hour after the enema. The tests were negative in two subjects with achylia and one with cancer of the stomach.

Practical Significance of Lactation Atrophy of the Uterus. W. Thorn.—According to Thorn, the number of women unable to nurse their children is constantly increasing in Germany. It almost seems, he remarks, that Germany is taking its place beside France, at the head of the procession. Progressing civilization entails this inability to nurse, as exemplified in the history of India, Greece and Rome. Mothers unable to nurse their offspring are less resistant and suffer from various general and local disturbances. The physiologic process—lactation atrophy of the uterus—is interfered with. Under normal conditions, the body of the uterus becomes atrophied during lactation, and normally, is accompanied by amenorrhea, although ovulation continues. Complete regeneration follows after the weaning of the child, or at latest within six weeks. If the cervix or ovaries are involved in the atrophy or if it extend beyond, the amenorrheic nursing woman should be strengthened by abundant nourishment, and the nursing should be interrupted at intervals, to restore the atrophy to its physiologic limits. If this can not be accomplished, the child must be weaned. No woman, especially if amenorrheic, should nurse for more than a year, and eight months should be the average for moderately strong, amenorrheic women unless in special circumstances. No local treatment of the atrophy is necessary, not even for the frequently accompanying retrodisplacement. An acute intercurrent disease does not interfere with regeneration. If the atrophy persists for more than six weeks after weaning, local treatment should be instituted as a supplement to general tonic measures. During the period of atrophy the walls of the uterus are very soft and thin, and consequently no instruments should be inserted, or should be employed only with extreme caution. Women who menstruate more or less regularly during lactation do not present this atrophy of the uterus. The cavity of the uterus in the typical amenorrheic cases becomes reduced to 4.5 cm. and the walls to a few millimeters thick, but the cervix and the ovaries retain their normal size. Frommel has reported that regeneration did not occur in any of the 28 cases he observed, but his material was all gynecologic. All of Thorn's 25 patients returned to normal conditions at the normal time. They were healthy obstetric cases.

Importance of the Pulse in the Puerperium. O. Aichel.—Every surgeon compares the pulse before and after an operation. Aichel proclaims that this should be done also in obstetric cases. The physician should record the patient's pulse at some time during the pregnancy. He will then have a base for comparison with the pulse during the puerperium, and he will find this comparison a most valuable means of determining the course of events, far more reliable than the temperature curve. In several cases he has found that the pulse remained rapid, although the temperature had returned to normal, and invariably some exacerbation or complication later explained the behavior of the pulse. In 5 per cent. of his cases, Aichel found a pulse of 100 during the pregnancy and consequently was not disturbed when the pulse remained at 100 during the puerperium. The pulse is slower when the subject reclines, and therefore the pulse during the puerperium may be expected to be a trifle slower than when taken during the pregnancy unless the subject is reclining.

Cyclic Albuminuria. P. Edel.—The measures that have a favorable influence on albuminuria owe their efficacy, Edel believes, to the fact that they promote the circulation of the blood in the kidneys. The heart should be exercised and trained in cases of albuminuria and nephritis, as systematically as in case of cardiac affections. An energetic walk, in his experience, has always suspended the cyclic albuminuria, if stopped short of fatigue, while a dragging, lounging walk had no influence. Another important element in the treatment of cyclic albuminuria is the food. He ordered more nourishing food, at shorter intervals, with systematic exercise and the albuminuria vanished completely in eight weeks, after it had persisted for eight months unaffected by all kinds of treatment. This experience has been repeated in three patients, and he considers himself justified in proclaiming the importance of this method of treating cyclic albuminuria, evolved from study of the pulse of the patients. Whenever the pulse exhibited the influence of increased resistance to the circulation, albuminuria occurred, but when the pulse was normal, the urine was normal too. By measures to regulate the circulation, the pulse was restored permanently to normal and the albuminuria vanished at the same time.

Therapeutische Monatshefte (Berlin), November.

Internal Disinfection in Infectious Diseases. L. Weill.—Inhalation of the steam from a boiling solution of sublimate, three times a day for four weeks, had a remarkably curative effect in a number of cases of acute tuberculosis. The temperature invariably fell, sometimes as much as two or three degrees, and catarrh of the apices, and glandular affections rapidly healed. Glands with connective tissue formation or in caseous degeneration were not affected. In cases of typhoid fever, the internal disinfection was accomplished by means of rectal injections of a pint of a 1 to 10,000 or 1 to 20,000 solution of sublimate, retained as long as possible. The effect on the temperature was equally pronounced. In a recent typhoid epidemic the cases thus treated were unmistakably shorter and less severe than others which received merely the usual treatment. Another advantage is that the stools are already disinfected before they are evacuated, thus reducing the danger of contagion.

Lecithin in Therapeutics. A. Gilbert.—Consumptives and neurasthenics thrived remarkably on pills containing 0.1 to 0.5 gm. lecithin, or it was administered in subcutaneous injections of 0.05 to 0.15 gm. repeated every second day. The appetite and weight increased, and no evil effects were observed even on prolonged administration of lecithin derived from eggs.

Therapie der Gegenwart (Berlin), November.

Bismuth Treatment of Gastric Ulcer. W. Fleiner.—In the treatment of a gastric ulcer the aim is to induce the stomach to contract to the smallest possible size and keep it in this condition. The slightest relaxation of the tonus of the stomach walls must be combated with ice-bags or hot applications or the thermophore. If the bottom of the ulcer is fibrous and indurated, the edges do not become approximated even when

the stomach is contracted to its minimum. The surface of the ulcer is thus exposed to mechanical and chemical irritation from the contents of the stomach, with consequent irritation, pain, vomiting, etc. It is possible to supply in these cases an artificial covering for the exposed surface of the ulcer by means of bismuth. The patient should drink, an hour before meals, 100 to 200 gm. of water into which 5 to 10 or 20 gm. of bismuth have been stirred. He should then lie down on the affected side. In order to cleanse the stomach, 100 to 150 gm. of hot Carlsbad or Vichy water should be taken an hour before the bismuth. An ulcer will sometimes heal on a milk diet without medicines. The bismuth may be needed only during the transition from fluid to solid food. In case of an old, fibrous ulcer, the bismuth should be immediately preceded by thorough irrigation of the stomach until the water emerges clear. When the ulcer is complicated by stenosis of the pylorus, this treatment will relieve but will seldom cure, and an early gastro-enterostomy will relieve and heal during the time that is wasted on medicinal measures. The bismuth is contra-indicated in case the ulcer has formed in or developed a recess in the stomach wall. In the only case of this kind, in Fleiner's ten years of experience, the morning rinsing of the stomach brought up the bismuth crystals from the day before, not white as usual, but black, showing that the bismuth had undergone the chemical change which otherwise occurs only in the intestines.

Gazzetta Degli Ospedali (Milan), October 27.

Feeding in Febrile States. G. Cavallero.—The conclusions of this long study of the subject are that the same rules that regulate the feeding of patients in acute fevers should apply, although less strictly, to chronic febrile conditions. The food should be adapted to compensate for the exaggerated metabolism, which includes an increased destruction of the organic albumin, due partly to the lack of sufficient nourishment and partly to the bacterial intoxication. The products derived from the destruction of albumin, fats and carbohydrates are less completely oxidized than in normal conditions. A febrile patient requires approximately 25 to 30 calories per kilogram of body weight. Of this amount 4 or 5 can be supplied in the form of albumin, 5 or 6 as fats and 16 to 20 as carbohydrates. The chronic febrile patient requires more calories, possibly 35 to the kilogram of weight. He has to combat, besides the fever, some suppurative process in most cases. The depressing influence of the bacterial toxins must be counteracted by stimulants, tea, coffee or alcohol.

November 5.

Typhoid Peritonitis from Propagation. Queirolo.—The peritoneum has a wonderful resisting power against infection, but when the organism is under the influence of the typhoid toxins, this defense is broken down and peritonitis may ensue, either from perforation, or by infection from contiguity or propagation. Queirolo has examined cadavers which presented the typical lesions of typhoid peritonitis subsequent to a typical attack of typhoid fever, but the microscope was unable to disclose the slightest trace of a perforation at any point in the intestines. He states that a closed cavity is not necessary to enhance the virulence of the bacilli in the intestines. They may become virulent during typhoid fever at any time, and the rarity of peritonitis is due to the effective defense in spite of the lesions in the intestines, the gaping lymphatics, etc. Peritonitis does not occur without some lesion in the peritoneum. This may occur in the course of typhoid fever as a consequence of the general intoxication, which may possibly have a special predilection for the peritoneum in some cases. Another factor which may co-operate is the paresis of the intestines in typhoid fever. It realizes the two ideals, enhanced virulence of the bacteria and their prolonged sojourn at one spot. Study of typhoid patients has demonstrated that the typhoid process in the mucous membrane of the intestine may become propagated to the peritoneum by means of the veins and perivascular lymph routes without injuring the muscular coat, although traversing it in these vessels. He describes the autopsy findings in a typical case of typhoid propagation of this kind, which confirm his views in every point. He believes that the colon bacillus is the usual causal agent of peritonitis by propagation, although by no means specific. The differentiation of peritonitis from perforation and from propagation is extremely difficult, and yet surgical intervention, which is often the only means of saving life in the former, is contra-indicated in the latter. The symptoms occur in each with the same tempestuous onset. The sudden drop in the temperature which some have mentioned as the invariable accompaniment of a perforation, does not always occur. The behavior of the pulse, the vomiting, the composition of the blood, are about the same in each form of peritonitis. The persistence of the liver and spleen dulness would aid in the differentiation, but can only be utilized too late for practical benefit. The amount of gas escaping through the perforation may be insufficient to mask this dulness, and thus allow its persistence. In this event, however, there would be no intestinal and peritoneal meteorism. Tardy disappearance of the liver and spleen dulness in the course of peritonitis from perforation, is probably due to the rigidity and contraction of the abdominal muscles. The prognosis of peritonitis from propagation is grave. Only about 50 per cent. recover. The treatment should aim to sustain and stimulate the heart, kidneys, innervation, etc., but the main point is to free the intestines from bacteria. This is the doctrine which Queirolo has been proclaiming so long and so urgently. He insists that peritonitis from propagation should not be allowed to develop. The intestines should be managed in such a way in typhoid fever that no favorable conditions for the development of peritonitis from propagation should be allowed to exist. The intestines should be evacuated with calomel and thoroughly disinfected and the feeding should be exclusively rectal, entirely avoiding the gastric route. He finds that ice-bags on the abdomen diminish the natural resisting powers of the peritoneum.

Hydatid Fremitus in Simple Ascites. A. Cavazzani.—An extensive and typical hydatid fremitus was observed in the abdomen of a subject with simple ascites from cirrhosis of the liver. Studying the conditions that favored its production they were found to be the combination of extremely thin walls, high tension and the contact of loops of intestine, full of gas and fluids, held against the abdominal wall by the enlarged malarial spleen. Cavazzani reproduced these conditions artificially and was able to produce the hydatid fremitus at will.

November 7.

The Clinical Value of the Diazo-Reaction. A. Lamari.—Judging from his study of 800 tests for the diazo-reaction, Lamari does not ascribe any absolute diagnostic value to it, but in connection with other signs it may afford very valuable information. He states that the gastric or other organic juices may exhibit the diazo-reaction when it is absent in the urine. It is influenced by the medication, and diminishes as the amount of urine is increased. It appears in certain urines only after they have been boiled down or decolored with lead nitrate. Salol attenuates and naphthalin accentuates the reaction. In one of his patients the reaction became positive in the gastric juice after it had disappeared from the urine.

November 17.

Effects of Tetanus Toxin in Relation to Its Entering Point. G. Tizzoni and M. Collina.—There is a great difference between the effects of tetanus toxin when it is injected under the skin or under the dura or directly into the circulation. The two latter methods require much larger doses to prove fatal in rabbits. It seems to be evident that a certain portion of the toxin in these cases is neutralized by the blood or cerebrospinal fluid. In case of subcutaneous injection, the phenomena of exaggerated reflex excitability predominate; injected into the blood the phenomena of muscular rigidity prevail, while the subdural injection, accompanied by a lesion of the surface of the brain, induces the classical picture of cortical irritation. With an endocerebral injection, the symptoms are those of lesions of the centers. The phenomena observed when the toxin is injected into the blood indicate that the element in the toxin which causes the convulsions is neu-

tralized by the blood. If the blood is extremely toxic in a case of tetanus it is probably a sign of an extraordinary production of toxin over and above what the blood can neutralize, and is thus an unfavorable sign. A great difference was observed in the tests between the behavior of Tizzoni's and Behring's tetanus toxin, indicating a different composition, and possibly the presence of accessory toxins. These accessory toxins, impurities in the serum, explain why the experimental successes were not confirmed on man, when purer toxins were used. Only when the serum obtained after inoculation with toxin containing these accessory substances is applied in a case in which these accessory substances also happen to be present, is a cure probable.

Brazil-Medico, October 15.

Intravenous Mercurial Treatment of Werlhof's Disease. A. LUSIGNOLI.—Six cases are described which apparently prove that hemorrhagic diseases are caused by some specific microorganism whose products pass into the blood. Scorbutus, purpura, etc., are all of the same nature, and differ merely in intensity. They can be cured by a daily intravenous injection of 1 to 3 mg. of mercury bichlorid, repeated daily for four to seven days.

Roussky Archiv Pathologii (Moscow), xi and xii.

Mechanical Treatment of Anasarca. A. BROIDE.—Dehio's rubber bandage and funnel for the mechanical treatment of anasarca has been applied in 15 cases with great success. It should not be used as a last resort, but should be applied in the early stages after scarification of the spot.

Typhoid Bacilli in the Urine. W. KLIMENKO.—Sixty-five patients with typhoid fever were carefully investigated to determine the persistence of the bacilli in the urine. They usually disappear by the third to the thirtieth day, but in a few rare cases, persisted a year. By administering a substance that has an antiseptic action on the urine it might be possible to disinfect such patients. Bacteriologic investigation of the urine might clear up obscure cases of typhoid fever.

Queries and Minor Notes.

REQUIREMENTS OF HONOLULU, CUBA AND MEXICO.

MARIONA, VA., Nov. 22, 1901.

To the Editor:—Can you give the law or laws governing the practice of medicine in Honolulu, Cuba and Mexico? Z. U. S.

ANS.—We have no verified copies of the laws of Cuba, Hawaii and Mexico at the present time. In Mexico it appears to be largely a matter of identification; an account of the preliminary requirements, which are very elaborate, was published in THE JOURNAL, Dec. 23, 1899. After all the affidavits, etc., it is said that the examination may or may not be required according to the judgment of the governor of the state in which one chooses to practice. It seems to be required in the City of Mexico, and may be elsewhere. Many foreign physicians practice without any license in Mexico, but this is dangerous.

New Patents.

Patents of interest to physicians, etc., November 19 and 26:

687,112. Uterine curette. Seth D. Bowker, Kansas City, Mo.
687,004. Hot-water bag. Frank E. Crawford, Lake Mills, Wis.
687,181. Hot-air bath. Frederick C. Dilthey, Rockville Center, N. Y.
687,139. Nasal cup. Wm. J. Evans, New York City.
686,855. Making a disinfectant. Wm. T. Kendrick, Montgomery, Ala.
686,859. Electric generator and distributor for medical treatment. Edwin L. Madden, Kanawha, Iowa.
686,947. Making carbonate of magnesia. Wm. Marsh, Manchester, Eng.
686,985. Syringe. John M. Miller, Dayton, Wash.
686,831. Invalid bedstead. Wm. A. Nason, Algonquin, Ill.
687,367. Hypodermic syringe. Chester M. Barton, Hatfield, Mass.
687,199. Pill-forming machine. Arthur Colton, Detroit, Mich.
687,617. Mouth illuminator. Edward Ebi, Cedar Rapids, Iowa.
687,376. Inhaler. John Harrison, New York City.
687,243. Massage machine. Francis King, San Francisco, Cal.
687,441. Vaginal syringe. Willis L. Short, Butler, Mo.
687,358. Box for holding pellets, capsules, etc. B. S. Whitehead. Newark, N. J.
687,363. Massage device. Paul E. Wirt, Bloomsburg, Pa.
35,315. Design, ice or hot-water bag. Christian W. Meinecke, Jersey City, N. J.
35,214. Design, blank for speculum blades. Charles J. Pilling, Philadelphia.
35,313. Design, massage device. Paul E. Wirt, Bloomsburg, Pa.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

PHOTOTHERAPY: (1) The Chemical Rays of Light and Smallpox. (2) Light as a Stimulant. (3) The Treatment of Lupus Vulgaris by Concentrated Chemical Rays. By Professor Niels R. Finsen. Copenhagen. Translated from the German Edition, with an Appendix on the Light Treatment of Lupus, by James H. Sequeira, M.D. Lond., M.R.C.P., Dermatological Assistant and Medical Officer in Charge of the Light Department at the London Hospital. Cloth. Pp. 79. Price, $1.75. London: Edward Arnold. 1901.

THE PRINCIPLES OF PATHOLOGICAL HISTOLOGY. By Harvey R. Gaylord, M.D., Professor of Surgical Pathology in the University of Buffalo: and Ludwig Aschoff, M.D., Professor and First Assistant in the Pathological Institute of the University of Göttingen, Germany. With an Introductory Note by William H. Welch, M.D., Baltimore. Illustrated with 81 Engravings in the Text and 40 Full-page Plates. Cloth. Pp. 359. Price, $7.50 net. Philadelphia and New York: Lea Brothers & Co. 1901.

THE ROENTGEN RAYS IN MEDICINE AND SURGERY, as an Aid in Diagnosis and as a Therapeutic Agent, Designed for the Use of Practitioners and Students. By Francis H. Williams, M.D. (Harv.), Graduate of the Massachusetts Institute of Technicology. With 391 Illustrations. Cloth. Pp. 658. Price, $6.00. New York: The Macmillan Co. 1901.

TOXICOLOGY. The Nature, Effects and Detection of Poisons, with the Diagnosis and Treatment of Poisoning. By Cassius M. Riley, M.D., Professor of Chemistry and Toxicology in Barnes Medical College, St. Louis, Mo. Cloth. Pp. 121. Price, $1.25. Published by the Author. 1901.

A PRACTICAL GUIDE TO THE ADMINISTRATION OF ANESTHETICS. By R. J. Probyn-Williams, M.D., Senior Anesthetist and Instructor in Anesthetics at the London Hospital. Cloth. Pp. 211. Price, $1.60. London, New York and Bombay: Longmans, Green & Co. 1901.

TRANSACTIONS OF THE TWENTY-THIRD ANNUAL MEETING OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION, Held at New Haven, Conn., May 27, 28 and 29, 1901. Cloth. Pp. 274. New York: Rooney & Otten Printing Co. 1901.

TRANSACTIONS OF THE ARKANSAS MEDICAL SOCIETY. Twenty-Sixth Annual Session, Held at Hot Springs, Ark., May 14, 15, 16, 1901. Paper. Pp. 253. Little Rock: Thompson Litho. and Ptg. Co. 1901.

THE PHYSICIAN'S VISITING LIST for 1902. Fifty-first Year of its Publication. Leather. Price, for 25 patients per day or week, $1.00. Philadelphia: P. Blakiston's Son & Co. 1901.

TRANSACTIONS OF THE RHODE ISLAND MEDICAL SOCIETY. Vol. VI, Part II. Paper. Pp. 277. Providence. Snow & Farnham. 1901.

PROCEEDINGS OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY. October. Paper. Pp. 41. Philadelphia: Published by the Society.

TRANSACTIONS OF THE CHICAGO PATHOLOGICAL SOCIETY. Nov. 11, 1901. Paper. Pp. 29.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Nov. 28 to Dec. 4, 1901, inclusive:

William B. Banister, major and surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., reporting on arrival, by telegraph, to the Adjutant-General of the Army.

Henry P. Birmingham, major and surgeon, U. S. A., relieved from duty in the Division of the Philippines and assigned to Fort Leavenworth, Kan.

James R. Church, lieutenant and asst.-surgeon, U. S. A., leave of absence on certificates of disability from the Department of Cuba is extended two months on account of sickness.

Harry A. Eberle, captain and asst.-surgeon, Vols., former orders so amended as to direct him to report on his arrival at Manila, P. I., to the commanding general for assignment in the Division of the Philippines.

Euclid B. Frick, captain and asst.-surgeon, U. S. A., member of a board at San Juan, P. R., to examine certain persons as to their fitness for appointment as lieutenants in the army.

Henry S. T. Harris, major and surgeon, U. S. A., leave of absence for seven days granted.

Arthur C. Heffenger, contract surgeon, previous orders requiring him to report for duty at Fort Constitution, N. H., revoked.

Merritte W. Ireland, captain and asst.-surgeon, U. S. A., on being relieved from duty as medical supply officer at Manila, P. I., by Major W. O. Owen (see below), to proceed to San Francisco, Cal., and report to the Adjutant-General of the Army for further orders.

James P. Kimball, lieut.-col., deputy surgeon-general, leave of absence on certificates of disability extended four months.

John S. Kulp, captain and asst.-surgeon, U. S. A., leave of absence for fifteen days granted, to take effect about Dec. 20, 1901.

John F. Leeper, contract surgeon, relieved from temporary duty at Jefferson Barracks, Mo.; on the expiry of his present leave of absence he will proceed from Casper, Wyo., to San Francisco, Cal., en route for duty in the Division of the Philippines.

Jose Lugo-Vina, captain and asst.-surgeon, Porto Rico Provisional Regiment of Infantry, member of a board at San Juan, P. R., to examine certain persons as to their fitness for appointment as lieutenants in the army.

William C. LeCompte, captain and asst.-surgeon, Vols., so much of orders of November 14 last as relates to Contract Surgeon William C. Le Compte is amended to read Captain William C. Le Compte, asst.-surgeon, Vols.

John A. Murtagh, lieutenant and asst.-surgeon, U. S. A., former orders so amended as to direct him on the expiration of his present leave of absence to proceed to Fort McPherson, Ga., to accompany a battalion of the 27th Infantry to San Francisco, Cal.

William O. Owen, major and surgeon, U. S. A., previous orders amended so as to direct him on his arrival at Manila, P. I., to report to the commanding general for duty as medical supply officer, relieving Captain Merritte W. Ireland, asst.-surgeon, U. S. A.

Charles Richard, major and surgeon, U. S. A., from Fort Leavenworth, Kan., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended December 7:

P. A. Surgeon H. H. Haas, detached from Norfolk Navy Yard, and to the *Kearsarge*, for duty with the marine detachment.

Asst.-Surgeon F. M. Furlong, when detached from New York Hospital, ordered home on sick leave for two months.

Asst.-Surgeon P. E. McDonald, detached from the *Constellation*, when discharged from Naval Hospital, New York, and ordered home with one month's sick leave.

Asst.-Surgeon W. M. Garton, detached from the Naval Academy and ordered to the Naval Hospital, New York.

Asst.-Surgeon J. B. Dennis, detached from the Naval Hospital, New York, and ordered to the Naval Academy, upon reporting of relief.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the twenty-one days ended Dec. 5, 1901:

Surgeon Eugene Wasdin, granted leave of absence for 21 days from December 19.

Surgeon W. P. McIntosh, to proceed to Illijay, Georgia, for special temporary duty.

P. A. Surgeon H. D. Geddings, detailed to represent the service at a conference of health officers at Ann Arbor, Mich., November 21 and 22. Upon adjournment of said conference to proceed to Detroit, Mich, for special temporary duty.

P. A. Surgeon A. R. Thomas, relieved from duty at Liverpool, Eng., and assigned to duty in the office of the United States Consul-General at Glasgow, Scotland.

Asst.-Surgeon R. H. von Ezdorf, granted leave of absence for two months and fourteen days from November 23.

Asst.-Surgeon J. F. Anderson, relieved from duty at the Immigration Depot, New York City, and assigned to duty in the office of the United States Consul at Liverpool, Eng.

Asst.-Surgeon V. G. Heiser, to proceed to St. Johns, N. B., for duty in the office of the United States Commissioner of Immigration.

Asst.-Surgeon Carroll Fox, relieved from duty at Port Townsend quarantine, and temporary duty at Port Townsend, Wash., and directed to report to Asst.-Surgeon J. F. Anderson for duty in the office of the United States Consul at Liverpool, Eng.

Asst.-Surgeon T. B. McClintic, granted leave of absence for one month from December 11.

A. A. Surgeon Francis Duffy, granted leave of absence for seven days from November 25.

Surgeon W. P. McIntosh, granted leave of absence for three days from November 26.

P. A. Surgeon H. S. Cumming, relieved from duty at South Atlantic Quarantine. Granted leave of absence for seven days from November 29.

Asst.-Surgeon G. M. Corput, directed to assume command of the South Atlantic Quarantine Station, relieving P. A. Surgeon H. S. Cumming.

Asst.-Surgeon J. S. Boggess, granted leave of absence for ten days from December 5, with permission to leave the United States.

A. A. Surgeon Felix Giralt, upon being relieved by A. A. Surgeon S. H. Hodgson, to rejoin station at Havana, Cuba.

A. A. Surgeon E. B. Hallett, granted leave of absence for two days from November 28.

A. A. Surgeon S. H. Hodgson, relieved from duty at Progreso, Mexico, and assigned to duty in the office of the United States Consul at Vera Cruz, Mexico.

A. A. Surgeon J. A. Rowles, granted leave of absence for four days from November 27.

Hospital Steward S. W. Richardson, relieved from special temporary duty at Buffalo, N. Y., and directed to proceed to Washington, D. C., and report to the Director of the Hygienic Laboratory for temporary duty.

A. A. Surgeon V. B. Gregory, directed to report for duty.

A. A. Surgeon J. S. Hough, relieved from duty at Hong Kong, China, and assigned to duty in the office of the United States Consul-General at Yokohama, Japan.

A. A. Surgeon S. B. Hunter, granted leave of absence for ten days from November 7.

A. A. Surgeon A. P. McConnell granted leave of absence for three days from November 27.

A. A. Surgeon C. L. Moore, relieved from duty at Boston, Mass., and directed to proceed to New York City, and report to Surgeon G. W. Stoner at the Immigration Depot for duty.

Surgeon H. W. Austin, to report at Washington, D. C., for special temporary duty.

Surgeon F. W. Mead, granted leave of absence for one day, December 10.

Surgeon H. R. Carter, detailed as inspector of the port of Solomons, Md.

Surgeon T. B. Perry, relieved from duty at Baltimore, Md., and directed to proceed to New York City, and report to Surgeon G. W. Stoner, Immigration Depot, for duty.

P. A. Surgeon Rupert Blue, relieved from special temporary duty at San Francisco, Cal., and directed to rejoin station at Milwaukee, Wis.

P. A. Surgeon H. S. Cumming, to proceed to San Francisco Quarantine, Cal., and report to Surgeon D. A. Carmichael for duty, reporting at Bureau en route.

Asst.-Surgeon W. C. Hobdy, to proceed to Elberton, Ga., for special temporary duty.

Asst.-Surgeon A. J. McLaughlin, to proceed to Cape Fear Quarantine, and assume temporary command of station during absence of Asst.-Surgeon T. B. McClintic, on leave.

Hospital Steward S. W. Richardson, relieved from temporary duty in the Hygienic Laboratory, Washington, D. C., and directed to proceed to Charleston, S. C., and assume charge of the Marine Hospital exhibit at the South Carolina Interstate and West Indian Exposition.

BOARD CONVENED.

Board convened to meet at Washington, D. C., Nov. 18, 1901, for the physical examination of candidates for appointment to the grade of second assistant engineer in the Revenue Cutter Service. Detail for the Board: Surgeon R. H. Woodward, chairman; Assistant-Surgeon B. S. Warren, recorder.

APPOINTMENT.

W. S. Jackson, of Michigan, appointed acting assistant-surgeon, for duty at Houghton, Mich., Nov. 12, 1901.

RESIGNATION.

Hospital Steward W. F. Schlaar resigned, to take effect Nov. 15, 1901.

CASUALTY.

A. A. Surgeon Stuart Eldridge, died at Yokohama, Japan, Nov. 16, 1901.

Health Reports.

SMALLPOX—UNITED STATES.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Dec. 6, 1901:

Alabama: Gilmer County, Nov. 26, 10 cases.
Illinois: Springfield, Nov. 1-30, 30 cases.
Indiana: Evansville, Nov. 23-30, 2 cases.
Kentucky: Lexington, Nov. 23-30, 4 cases.
Louisiana: New Orleans, Nov. 23-30, 2 cases, 1 death.
Maryland: Baltimore, Nov. 23-30, 1 case.
Massachusetts: Boston, Nov. 23-30, 103 cases, 8 deaths; Cambridge, Nov. 23-30, 1 case, 1 death; Lowell, Nov. 23-30, 1 case; Malden, Nov. 23-30, 1 case; Medford, Nov. 23-30, 1 case; New Bedford, Nov. 26-Dec. 2, 2 cases; Newton, Nov. 23-30, 1 death.
Minnesota: Minneapolis, Nov. 22-29, 4 cases; Winona, Nov. 23-30, 2 cases.
Nebraska: Nov. 23-30, Omaha, 4 cases; South Omaha, 16 cases.
New Jersey: Camden, Nov. 23-30, 5 cases; Jersey City, Nov. 24-Dec. 1, 11 cases; Newark, Nov. 23-30, 26 cases, 4 deaths.
New York: Buffalo, Nov. 9-26, 36 cases, 3 deaths; New York, Nov. 23-30, 16 cases, 2 deaths.
Ohio: Cincinnati, Nov. 22-29, 6 cases; Dayton, Nov. 23-30, 1 case; Youngstown, Nov. 16-30, 3 cases.
Pennsylvania: Allegheny City, Nov. 23-30, 3 cases; Lebanon, Nov. 23-Dec. 1, 4 cases; Norristown, Nov. 23-30, 5 cases; Philadelphia, Nov. 23-30, 113 cases, 14 deaths.
Tennessee: Memphis, Nov. 23-30, 2 cases; Nashville, Nov. 23-30, 2 cases.
Utah: Salt Lake City, Nov. 30, 1 case.
Vermont: Burlington, Nov. 23-30, 7 cases.
Washington: Tacoma, Nov. 16-23, 3 cases.

FOOD PRODUCTS FROM DISEASED ANIMALS.*

D. E. SALMON, D.V.M.

BUREAU OF ANIMAL INDUSTRY, DEPARTMENT OF AGRICULTURE.

WASHINGTON, D. C.

What effect may the food products from diseased animals have in disturbing the digestion and in causing more serious diseases in the human consumer? It is a question easily asked, and dismissed by many with the same facility, but who can supply the data that will convince the mind of the earnest student of dietetics?

From my point of view the subject is one which has been sadly neglected. There are few who stop to consider the millions of cattle and sheep, the tens of millions of swine and the hundreds of millions of birds consumed as food in this country every year. To watch the arrival of such animals at one of our great packing centers for a single day, fills one with a feeling of amazement at the enormous development of the stock-raising industry, and at the tremendous amount of animal food which our people require. But what we have seen at any one point is but a small part of what has been done at all of the fifteen or twenty packing centers. And this great flow of live animals from the farm to the abattoirs is constant and is more uniform than the flow of our great rivers. It goes on night and day, with only moderate variations as to quantity, every month, every week, and every day of the year.

Now picture in your minds for a moment the great flow of dairy products—of milk, of butter and of cheese—from the farms and creameries and factories to the consumers; these are produced by more than 16,000,000 cows. If these streams of nutritive material are liable to contamination, how important it is that they should be guarded at all points.

Unfortunately, animals are subject to a large number of diseases, from the simplest functional disorders to the most serious organic changes, and to the most deadly forms of contagion. The great scientific activity of the last quarter of the century just past has served to clear up the pathology of many of these diseases, and the educated veterinarian now knows the nature of the diseases he sees, and can appreciate fairly well the effect of various pathologic conditions upon the products of the affected animals. But outside of the veterinary profession, with comparatively few exceptions, the knowledge of animal pathology is fragmentary; the ideas concerning it are vague, distorted and misleading; the notions as to the details of sanitary precautions are crude, impracticable and insufficient. It is for this reason that I venture to introduce this subject and treat it in an introductory manner.

The federal meat inspection service has been by many misunderstood and misrepresented. It is a sanitary inspection rather than a commercial inspection. It is applied to meats shipped from state to state as well as to foreign countries. The first object of the inspection is to protect the health of the consumer. The one part of this inspection system, which is made primarily for commercial reasons, is the trichina inspection, which is only applied to pork intended for shipment to certain countries which require such an inspection. The trichina inspection is, however, but a small part of the federal meat inspection service and should not be permitted to obscure the efforts made in the general inspection service to protect the health of our own citizens.

The great difficulty in meat inspection is the question as to where to draw the line between meat that shall be passed as fit for food and that which shall be condemned. There are many carcasses with which there is no such question raised—the great majority are unquestionably good or unquestionably bad. But between these extremes there are all shades of gradation. I once saw a health officer condemn a number of fine carcasses of beef, because he discovered in the animals' intestines a few cysts containing cheesy matter, which he thought were actinomycotic, but which were really caused by a minute animal parasite, and which affected the quality of the beef no more than would a wart upon the animal's skin. At the same time there was hanging in a conspicuous place in the slaughter-house a carcass of beef affected with generalized tuberculosis, and literally filled with small tubercles. This was allowed to go upon the market unchallenged. If the man who passed upon these carcasses had been selected because of his knowledge of pathology rather than for his efficiency in politics, he would undoubtedly have condemned the tuberculous carcass without interfering with that showing the verminous nodules in the intestines.

But it is not alone ignorance with which we have to contend. Sanitary questions are complicated with questions of fraud. For instance, the flesh of dogs is esteemed by the people of some countries, and, so far as I am aware, it is nutritious and not injurious. An American meat inspector could not allow the sale of dog meat, however, because it is repugnant to our people; it would not be purchased and consumed if its nature were known, and its sale would constitute a fraud. The flesh of horses and mules, which is eaten in civilized countries to a much greater extent than that of dogs, is nevertheless often condemned with us because it is usually sold

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Physiology and Dietetics, and approved for publication by the Executive Committee: Drs. James Weir, Jr., Winfield S. Hall and Elmer Lee.

in a fraudulent manner as the flesh of cattle. The flesh of goats is probably in most cases sold as mutton, but it is not likely that the carcasses are ever condemned for that reason. These examples are mentioned to make clear the arbitrary manner in which the flesh of some species of animals is often condemned, while that of other species, also sold fraudulently, is allowed to go to the consumer without protest. These are questions of habit and custom rather than of sanitation.

Let us go a step further and briefly consider the question of special physiologic condition of the animal at the time of slaughter. The meat of an old boar or a stag (castrated after becoming adult) has a strong, offensive taste and odor and is likely to cause loss of appetite and possibly nausea in the delicate and sensitive consumer. Should such meat be invariably condemned? Probably not, because there are consumers who are neither delicate nor sensitive about such matters, and who prefer to use such meat because it is sold at a lower price, while the odor and taste reveal its nature to those who object to it.

It is by no means infrequent that female animals in an advanced stage of gestation are found in the slaughter-houses. In most countries these are not interfered with by the sanitary authorities, but the United States inspectors are instructed to condemn them and prevent their slaughter for human food. I have often been asked to give my reasons from a sanitary point of view for this course. My justification is twofold: 1, a consumer would not knowingly purchase such meat, and its sale is as much a fraud as is that of horse meat, and 2, while the animal is, strictly speaking, in a physiologic condition, it is not in its usual physiologic condition, nor is the change one which is calculated to improve the quality of the meat. The respiration of the fetus throws a large quantity of waste products into the blood of the mother. In the preparation for parturition the circulation is disturbed; there are material morphologic changes in the reproductive organs and parts connected with them; some of the liquids of the body, as for example the milk, are considerably changed in composition. The flesh of an animal in this condition is, in my opinion, objectionable, although I do not know of any cases in which it has injured the consumer.

It is desirable that the shipment for slaughter of animals advanced in pregnancy should be discouraged, since they are more liable to injury than others, the fetus being often found dead, and frequently more or less decomposed. In such cases there may be considerable inflammation of the uterus, and absorption of septic material. The carcasses of such animals must, of course, be condemned. For these reasons inspectors of the Bureau of Animal Industry are instructed to condemn all animals which are within two weeks of the time of parturition.

Females in which parturition has recently occurred are also condemned as unfit for food. It is astonishing to see how many calves, lambs and pigs are dropped en route or in the stock yards. Sometimes this happens as the animals are on the way to the killing floor. Often parturition is hastened by bruises, crowding in the cars, fright or other causes. In this case there is more disturbance of the mother's health—weakness, retention of the membranes, offensive discharge, feverishness and septic absorption. Such animals are not in the condition to produce a safe and wholesome meat for human consumption. And yet there is always difficulty in drawing the line up to which pregnant animals may be slaughtered, and beyond which they must be condemned; or to which parturient animals must be condemned and beyond which they may be passed as fit for food.

A very large number of animals come to market with bruises and injuries which more or less affect the carcass. Last year for this cause we condemned, in round numbers, carcasses or parts of carcasses, of 4500 cattle, 1000 sheep and 12,300 hogs. In some of these the carcasses were only slightly bruised, in others the injuries were extensive, and in some cases complicated with abscesses, septic infection and gangrene. These are serious conditions which require careful consideration on the part of the inspector in order to determine when a part of a carcass only need be destroyed, or when it is necessary for the protection of the consumer that the whole carcass should be condemned.

There are certain animal parasites encountered which are capable of infesting man, and which may cause slight illness or serious disease. We sometimes find the cysticercus bovis or larval stage of the tenia saginata—not a very dangerous parasite, but one which most people would prefer to avoid. More dangerous than this is the cysticercus cellulosæ, which gives rise to the tenia solium of man. As there are conditions under which the larval stage of this tapeworm may develop in the human subject, causing serious disorders of important organs or even death, it is essential that the parasite should be recognized and infested meat destroyed. The most dangerous of this class of parasites, and one which is apparently becoming more common in this country, is the echinococcus, the cause of hydatid disease. The bladder worm may be found in almost any part of the body of the meat-producing animals, and especially in the lungs and liver of cattle, sheep and swine. Last year it was found in 204 cattle, 46 sheep and 487 hogs—a total of 737 affected animals. The adult tapeworm lives in the dog, and this animal scatters the eggs broadcast to infest other animals. The parasite is not directly transmissible from these animals to man, but the life cycle is completed by dogs eating the affected organs of the meat-producing animals. Man becomes affected from the eggs of the mature worm excreted by the dog. Hence the importance of meat inspection to discover the echinococcus in animals, and to secure their destruction before they can be devoured by dogs. In Iceland and some parts of Germany, statistics show from 2 to 2.5 per cent. of the people affected with the echinococcus disease.

The trichina spiralis is in this country a common parasite of hogs. As the hogs run in the large packing centers, about 2 per cent. are found affected, but in some sections of the country and at some seasons the proportion may be much less. On the other hand, special lots of hogs may be infested in a much greater proportion. Dangerous as is this parasite, it appears next to impossible to protect the consumer by inspection. A microscopic examination reveals most of the cases, but some will escape the closest scrutiny. It appears better, therefore, to rely upon cooking to make swine flesh safe, rather than to trust to microscopic inspection, which at the best lessens without entirely removing the danger.

There are inflammations of all organs and various infectious diseases of animals encountered, which are accompanied by fever, emaciation and organic changes, and which affect the quality and wholesomeness of the flesh. Among these diseases deserving of notice are the scabies of sheep and Texas fever of cattle. Both of these

diseases are under control, but cases are still occasionally found at the slaughter-houses. The most common of all diseases are hog cholera and swine plague. Not less than 32,859 carcasses were condemned last year because affected with these diseases. Actinomycosis is a disease which is also quite frequently seen, 2427 carcasses of beef being condemned in whole or in part last year on account of it.

What is the effect upon the human consumer of eating the flesh of animals affected with an ordinary inflammation, say a pneumonia or a pleurisy? Or, going farther, what is the effect of eating the flesh of animals suffering from infectious diseases not transmissible to man? It appears to me that our knowledge is somewhat deficient in regard to this, but certainly the habits and views of our people, coupled with the known danger from toxins liable to be developed in such diseases, and the more rapid decomposition of the flesh of diseased animals which generally occurs, should be sufficient to justify condemnation. In general, the more pronounced the lesions found in the carcass, the more certain the inspector may be of his diagnosis and of the necessity of withdrawing the flesh from the open market. It is hardly necessary to explain to physicians that where there are over 30,000 carcasses condemned for diseases such as hog cholera and swine plague, there will be many carcasses found in which the lesions are not clear and where there is reason to doubt if they are due to these diseases. It is with such equivocal cases that the conscientious inspector finds his greatest difficulty and embarrassment; for, on the one side it is his duty to protect the public health, and, on the other, it is no less his duty to avoid the needless destruction of property.

The most common diseases found among cattle are tuberculosis and actinomycosis, and, with the exception of hog cholera and swine plague, tuberculosis is the most common disease found in swine. With neither tuberculosis nor actinomycosis is it practicable or desirable to condemn to utter destruction the entire carcass of every affected animal. Both diseases in the early stages are usually localized and circumscribed, and without any effect upon the body as a whole. The lesion may be but a tenth of an inch, a fourth of an inch or half an inch in diameter. In such a case it would be an unjustifiable waste of the general food supply and an unwarrantable destruction of property to destroy the whole carcass, though the affected organ should be in every case condemned.

In Germany the whole of a tuberculosis carcass is condemned only when there is great emaciation or when a number of organs are affected and the location of the lesions indicates that the infection has been carried through the blood stream. With us we condemn the carcass not only when there is emaciation or a generalization of the lesions, but also when the lesions in any organ or organs are of such number and size as to indicate that the system at large may have been affected, either by inflammation, by the mixed infection, by the secretion and absorption of pus or toxic principles, or by interference with the general nutrition of the body.

With swine it is necessary to be even more particular than with cattle, because the disease is of a more acute type and there is a much greater tendency to generalization of the lesions. The increasing prevalence of this disease among swine is most disquieting to the sanitarian and deserves the early and serious consideration of all who are interested in limiting the ravages of this disease.

Turning now to the question of milk from diseased animals, I doubt if anyone who has not been actually engaged in the inspection of dairy stables can quite appreciate the condition in which the cows of some of these are liable to be found. Inflammation of the udder is a very common affection and may subside after a few days or may terminate in an abscess. Very often there is catarrh of the milk ducts, or an abscess opening into these channels, and in either case the secretion passes away with the milk.

In other cases there may be infective inflammations of the udder or tuberculosis of the organ, when, of course, the condition is even more serious. The extent to which tuberculosis may develop in the cow's udder and the tremendous quantity of thin tubercular material which may be mixed with the milk in such cases was demonstrated by the specimens which I exhibited at the meeting of the American Medical Association last summer.

Tubercle bacilli may be present in the milk of tubercular cows, however, when there are no signs of tuberculosis of the udder. The investigation of this subject has been greatly aided by the tuberculin test, which directs our attention to the affected animals. It has been proved that in some countries from 40 to 50 per cent. of all the cows have tuberculosis. In the United States the proportion is very much less, being probably not over 5 per cent. in our worst affected states. Yet, there are many herds here as badly affected as the worst herds of Europe. It is not uncommon to find 85 to 95 per cent. of reacting animals in a large dairy herd. The proportion of these which give infected milk depends upon the extent to which the disease has progressed in the animals. Some investigators have found infection in the milk of only those cows which have tubercular lesions in the udder, say in 1 or 2 per cent. of reacting cows. Others equally competent have found infection in the milk of 12, 15, 33 and even 66 per cent. of the reacting cows which were investigated.

I have not the time, even had I the data and were disposed, to point out the effect upon the human consumer of taking into his digestive canal the meat and milk of diseased animals. This paper is designed to be suggestive. Its aim is to call attention to conditions of more or less seriousness which are constantly found in a certain proportion of the animals shipped to market for human food. Since the federal inspection has been established for meat shipped in the interstate trade, the tendency is to send the known diseased animals to the slaughter-houses which kill for the local trade and have little if any inspection.

Unquestionably, the products of many badly diseased animals get upon the market and are eaten. What effect does this have upon the public health? What proportion of the cases of diarrhea, cholera morbus, etc., are due to such food? What is the extent of the danger from taking large quantities of tubercle bacilli in either rare meat or in uncooked milk? These are dietetic questions which it appears to me might well receive more attention. Without doubt there should be greater efforts than have yet been put forth in this country to secure a pure and wholesome food supply. Those who are working in this direction need the encouragement and aid of the general practitioner of medicine, I might say of the whole medical profession. They need even more than this—the experience and knowledge which are gained

by the men in the active practice of medicine. Would it not be well to have more co-operation and a more frequent exchange of views?

DISCUSSION.

DR. CHARLES M. HAZEN—I wish Dr. Salmon in closing might say a few words about the disturbances not amounting to pathologic conditions. For instance, the question of venison killed after a long chase and without bleeding being fit for food. Such questions would be interesting in this discussion.

DR. WINFIELD S. HALL, Chicago—I think this paper opens up an exceedingly wide field for research. How wide a field do the experiments now being conducted cover and are the questions asked in line for being solved in the Washington laboratories, and especially, how far can tuberculous milk be taken without endangering the health?

DR. DAVID PAULSON, Chicago—I have become acquainted, to a certain extent, with the benefits which are derived from the efficient work that is performed under the direction of the government, as outlined by Dr. Salmon. It is unfortunate that as far as Chicago is concerned it is still possible to dispose of diseased cattle to smaller slaughter houses outside of the regular packing-house district. The fact that animals are being continually killed in these smaller slaughter houses without any suitable examination and their flesh placed upon the market in Chicago, should certainly cause us not to relax our efforts in this direction until some definite provision is secured that fully covers this ground.

DR. R. HARVEY COOK, Oxford, Ohio—I would like to ask Dr. Salmon to give more in detail the reason why an animal during parturition is not good for food, other than from an esthetic idea and also from the fact that an animal is at this time more suspectible to disease.

DR. SALMON, in reply—I regret to say that there are many questions connected with the subject that I am unable to answer, especially with regard to the effect of exhaustion and fright on the flesh of the animal. The effect on deer chased by dogs is something of the same sort as that which happens to animals shipped long distances to market. We have a Federal law in this country that animals should be unloaded as often as once in 28 hours for feed, water and rest. Like many other statutes, it is honored chiefly by paying no attention to it. I have been for several years sending out men with stock trains and getting evidence against the railroad companies and bringing prosecutions. A number of convictions have been made, but they have not had as much effect as would be supposed. Persons who ship stock to marked want to get it through as soon as possible. There is surprising barbarity exhibited in the shipping of food-producing animals to market. I have seen cases in which animals in hot weather have been kept in stock-cars without food, water or rest for 96 hours. When unloaded in stockyards they distend themselves enormously with water, which puts them in a worse condition than when they were unloaded. I believe that that kind of meat is not in the most wholesome condition for those who consume it. Just what effect it may have on the consumer I do not know. I have no data, but believe that many of the minor troubles which occur are due to such cases. Every physician knows that there are many illnesses for which he can not account. When we consider the amount of meat consumed which is shipped in that way, I think we will agree that there must be a considerable effect on the health of the consumer. There is an opportunity for a great deal of close observation and experimentation to show the importance of correcting such conditions.

In regard to tuberculous milk, I had a paper before another section in which I took up the subject more in detail than I could here. I am a firm believer in the danger of milk from a tuberculous cow. There are a number of udders in the Pathologic Exhibit which show to what extent tuberculosis may invade the mammary glands. This morning the specimens were so solidly frozen that I could not trace the connection of the tubercles with the milk ducts. I have, however, seen cases in which the whole gland was practically a mass of liquid caseous material having free connection with the milk ducts and was passing out in tremendous quantities with the milk. This only happens in a few cases. When we consider that, in large numbers of tests, 20 to 50 per cent. of the animals are found infected and that one to two in every hundred have tuberculosis of the udder we see that in a great many cases the milk must be infected.

There has been some difference of opinion as to whether the milk was infectious when the mammary glands were free from tubercular deposit. A number of experiments have been made showing that a considerable proportion of tuberculous cows give infectious milk even when the udders are apparently healthy. The proportion of cows which have reacted to tuberculin and in which infection has been found in the milk varied from 5 to 66 per cent. When you have herds of cows of a hundred animals with 75 per cent. of them tuberculous, as is often the case, and a third giving infectious milk, there is a tremendous quantity of infection spread through the milk of these herds.

You may be aware that many physicians have denied, with more or less positiveness, the danger of tuberculosis from infected cows, either from the meat or the milk. Postmortem examinations of adults seem to confirm their views so far as they go. However, they are not as complete as we should like to see them. With children the case is otherwise. Statistics show an entirely different condition in the production of tuberculosis of the abdominal organs from that in tuberculosis of the lungs; an indication that as tuberculosis in cattle has increased, tuberculosis in children has also increased.

In regard to the effect of gestation upon the flesh of animals, I believe that the physiologic changes which occur in the last stages of the period of gestation do affect the general health. I think that the waste products from a fetus which are thrown into the circulation of the mother have a certain effect upon the flesh of the animal. I think also that the physiologic preparations for parturition must have great effect. We know the effect upon the composition of the milk and it must have almost equal effect upon the composition of the flesh. Yet, as I have said, we have very little data to show what bad effects the meat has upon the consumer. I would myself rather eat horse or mule flesh than eat the flesh of animals in the last two weeks of the period of gestation, and I think most people would feel as I do. The sale of the meat, therefore, is just as properly prohibited as would be the flesh of other animals not usually used for food.

TUBERCULOSIS IN THE MIDDLE STATES AND ITS CURABILITY.*

JOHN A. ROBISON, A.M., M.D.

Attending Physician to the Cook County and Presbyterian Hospitals; President Chicago Society of Internal Medicine; Secretary Illinois Society for the Prevention of Consumption.

CHICAGO.

When asked to present a paper on this subject I consented willingly, but it was willingness born of ignorance; I had no idea of the task before me. On investigating the literature on the subject of tuberculosis in the Middle States, I found that the mass of information concerning the climatology of these states and the factors which might cause or cure consumption was very meager. The subject soon outran the bounds of a twenty-minute paper. Therefore, I have arbitrarily selected the following states for consideration: Michigan, Ohio, Indiana, Illinois, Kentucky, Wisconsin, Minnesota, Iowa, Missouri, North and South Dakota, Nebraska, and Kansas. They lie between the Appalachian system of mountains on the east and the Rocky

*Read in a Symposium on Tuberculosis at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee of the Section.

mountains on the west, the Mississippi river draining the valley which slopes toward its shores. The altitude of this valley varies from 400 to the highest mountain tops of 3000 feet. But the greater portion of the valley is free from mountains or hills of any great altitude. In order to understand the conditions that might influence the course of disease in tuberculous patients in this region, the following is a brief description of the climates and physical characteristics of the various states:

Michigan, owing to its wide extent of latitude, has a varying climate, being quite mild in the southern part, but cold and rigorous in the winter in the northern part. There is a difference of about seven degrees between the temperature any given day in the northern and southern part, but the climate is healthful and the death-rate low. The upper peninsula of Michigan is rugged and rocky, broken up by hills in the western section which rise to a height of 2000 feet, while the lower peninsula is composed of plains and tablelands, with occasional prairie and considerable timber.

The annual mean temperature of Ohio is from 50 to 54 degrees, the warmest section being the southwest, on the Ohio river. The climate is mild and healthful, although sudden changes are liable to occur. Ohio has no mountains, although the interior of the state is 1200 feet above the sea level. From this elevated region the surface slopes to Lake Erie on the north 565 feet above the sea, and the Ohio river on the south 430 feet above the sea level. The great divide which makes the watershed passes diagonally across the state from the northeast to the west. The soil is fertile and extensive forests of hard wood abound.

Passing west into Indiana we find a variable climate, especially in the winter when the winds prevail from the west and northwest from the lakes. The state, however, is generally healthful, and the death-rate is low. The state has few hills, but is principally composed of level or undulating land, the highest elevation being 540 feet on the Ohio river at the mouth of the Wabash. The country near the lake is sandy.

The climate of upper Illinois is healthful, its proximity to the lake securing purity of the air, and the country is swept by bracing lake breezes. The lower part of the state suffers along the river bottoms and the swamp lands from malaria. The lowest altitude is 340 feet, and the highest 1150 above the Gulf of Mexico, the state being generally level, the soil very rich, especially along the river bottoms where a soil of vegetable mold forty feet in depth is found and heavy crops of corn have been raised many years without rotation or fertilizing. Illinois stands fifth in the list of mortality from consumption, which must be due to the fact that Chicago furnishes so large a number of cases as to increase the state's death-rate.

Kentucky affords a climate which is generally delightful, the mean average being 57 degrees F. The greatest rainfall is in the spring and winter, the summer and fall being usually dry. It has a splendid record for healthfulness. It is a tableland sloping gradually from the southeast to the northwest, the spurs of the Cumberland mountains breaking the southeastern part. None of the summits of this spur reach over 3000 feet altitude. The eastern half of the tableland has an average altitude of 1000 with ridges 500 feet higher.

Going to the extreme north we find Wisconsin, whose climate is tempered by the great lakes. Great changes do not occur suddenly, although a great deal of snow falls in the north. The winters are equable and the climate is bracing. The summers are short and hot, while the autumn is delightful. As a whole the climate is healthy and invigorating. The surface of the state, for the most part, is a great plain, varied only by the cliffs bordering the rivers and lakes, and elevated from 600 to 1500 feet above the sea. The northern part of the state is covered with immense forests of pine and hemlock.

Minnesota's salubrity of climate is well known. The purity of the air and the dryness of the winters has given the state a well-deserved reputation as a resort for pulmonary invalids. If I mistake not, the summers are warm, with breezy nights; the winters are cold, clear and dry, with a light snowfall. The surface of the state is an undulating plain with an average elevation of 1000 feet above the sea, but in the northeast there is a group of low sand hills, which rise about 600 feet higher. One thirty-fifth of the entire area is covered by lakes, which are in the region of heavy forests. That the state is free from influences that tend to develop consumption is proved by the fact that it stands low in the group of states having a large number of deaths from this disease.

Iowa is one of the healthiest states in the union; malarial, endemic and epidemic diseases are rare. The winters are severe on account of the north and northwest winds, but not unhealthful, while the heat of summer is relieved by the breezes. The surface of the state is undulating and beautiful, with alternate prairies and forests, while the rivers are lined by bold bluffs and charming ravines. In the northern portion of the state there are small lakes which form part of the group extending into Minnesota, Dakota and Wisconsin. The highest point of the state is in Dickinson County, 1650 feet above the sea, and there is a gradual slope to the southeast until at the mouth of the Des Moines river the altitude is only 444 feet.

Missouri has the most rigorous climate of all the states in the middle group, as the winters are extremely severe, and the summers hot. The state, however, is healthful, notwithstanding its climate. The northern part of the state as a rule is level and undulating, while the southern part is broken by hills, ranging from 500 to 1000 feet in height, and mountain ranges, the Iron mountains in the southeast, and Ozark mountains in the southwest. The bottom lands of the Mississippi are extensive, having many lakes and lagoons with islands which are never submerged by the severest floods.

North Dakota has a dry and salubrious climate. The winters are cold and there are heavy snowfalls, and the winter is prolonged but not so severely felt as in the same latitude in Minnesota. The summers are hot and dry. The temperature ranges from 20 F. below to 100 above zero during the year. Consumption is almost unknown in the state. The greater portion of North Dakota is a rolling prairie in which are many streams and lakes, but no swamps or marshes. The altitude varies from 670 feet on the eastern line to 1900 on the western line, as at Ft. Buford.

South Dakota has a milder climate, the spring being earlier even than in the states further east. The climate is healthy and salubrious. Like its northern neighbor it is composed principally of prairie, rolling and interspersed with water-courses. In the southwestern portion commence the famous Black Hills, some of whose

peaks reach 7000 feet above the sea. The altitude of the state varies, as is well illustrated when you look on the map and note that Huron has an altitude of 753 feet, Yankton 1222, and Deadwood 4600.

Over the wide prairies of Nebraska sweep the mountain breezes and owing to the splendid drainage, the dry exhilarating atmosphere is untainted by malaria. Along its western boundary are the foothills of the Rocky mountains, and the commencement of the Black Hills, the drainage being toward the Missouri river. North Platte, about the middle of the state, has an altitude of 2841 feet, and the altitude rises as you journey westward.

Passing down into Kansas we find that the winters are comparatively mild, the summers hot but not oppressive, and the atmosphere extraordinarily pure and clear at all seasons. The pure atmosphere offers to persons suffering from pulmonary complaints great relief, and a chance for a continuous outdoor life. It has an elevation of 750 at the mouth of the Kansas river, but slopes upward to an elevation of 3800 feet on the western border. You can find cities where good accommodations can be obtained at various altitudes, as for instance, Wichita, 1366 feet; Hutchinson, 1540 feet; and Garden City, 3000 feet.

In this brief review of the climates found in the middle states we fail to find any reason why tuberculosis should be more prevalent in any of these states than in the older states of the east or along the coasts of the Atlantic and Pacific oceans. In fact, there are many reasons why tuberculosis should be less prevalent, one fact alone being prominent, that is, in this vast region there are only fourteen cities having a population exceeding 100,000, and only fifty-three cities exceeding 25,000 in population. Crowded cities favor the development and spread of tuberculosis, which undoubtedly accounts for the fact that Illinois ranks fifth in the list of mortality.

In the list of states which have the greatest mortality from tuberculosis the following states in the middle region stand in this relation: Ohio third, Illinois fifth, Tennessee sixth, Missouri seventh, Kentucky eighth, Indiana ninth, Michigan thirteenth, Wisconsin eighteenth, Texas nineteenth, Iowa twentieth, Minnesota twenty-first, and Mississippi twenty-fourth. The reason Ohio, Illinois and Indiana rank so high is because they are states which contain large cities; Ohio has four cities of a population exceeding 100,000, and several which approximate this figure; Indiana has several large cities, and Illinois includes Chicago with its population of nearly two millions, and several well-populated cities. The southern states have a high death-rate owing to the prevalence of consumption among the colored people.

The average death-rate from consumption during the year 1890 throughout the United States was 268.81 per 100,000. But the average of the cities about the great lakes was much below this, while the average of the cities in the south was higher for reasons given above.

On account of the fertility of the Mississippi valley the country is rapidly being thickly settled, especially in the north, and this fact alone should increase the prevalence of consumption, but I am confident that the 1900 census will prove that there has been no increase. Therefore, there can be no intrinsic causes in the valley to increase the prevalence of the disease.

If there are no factors to cause the disease, except the increase of population, what are the possibilities for the cure of the disease in the middle states?

The answer to this question must hinge on the experience of observers who have treated consumption in the lowlands and the lower altitudes, and a searching analysis of the value of the higher altitudes in the treatment of the disease, and whether the home treatment of consumption with all the comforts the word home suggests, without the so-called climate, will produce as good results as the desired climate without the home comforts.

As to the results of treatment in the lowlands and lower altitudes we can only take the statistics as furnished by those who have observed the results at resorts situated in the respective levels. The results of treatment demonstrate the curability of consumption in the lower altitudes in percentages varying from 38 to 75, according to the stage of the disease. There are many authorities who claim that these results are not dependent on climate so much as on the supervision of the patient's daily life. If this be true, then there need be no argument that the disease may be cured in this region. The question would be rather, by what method can the cure be effected?

This problem seems to be working its own solution in a practical way, and that is by the establishment of sanatoria. Many of these sanatoria are established at points which do not present so many advantages as many places in the middle states, and yet they are doing good work.

The majority of these sanatoria have been established by private enterprise, individuals, or societies, independent of the various governments. But the good work done in these semi-private institutions has aroused the interest of governments, the crowned heads, and is now arousing a great interest among the legislators of the United States.

The list given by Knopf demonstrates the following facts: There are in Europe 127 sanatoria devoted to the consumptive, 35 in the United States, 2 in Canada, and 2 in Australia and Asia and 3 in Mexico; 15 of the European sanatoria are under municipal or governmental control, and 5 in the United States under municipal, county, state or government control.

The states have been slow to respond to the onward movement until within the last three years, when the states have been waking up to the fact that they should make provision for this large class of dependent patients. The first state to erect a sanatorium for the consumptive is Massachusetts, which completed a sanatorium in January, 1898. It has been in operation nearly three years with results encouraging to the highest degree.

Cook County has a hospital at Dunning in connection with the infirmary for advanced cases of consumption, and while the percentage of recoveries is necessarily low, there has been an improvement in the condition of many patients, owing to the betterment of their surroundings and appropriate treatment. The institution is doing a great deal of good by removing advanced cases from homes and lodgings where they are sources of contagion.

The sentiment in favor of state institutions is growing throughout the United States. New York will build a state hospital as soon as a site can be selected, to cost $200,000 and to accommodate 200 patients. A movement is also on foot to establish a sanatorium for

working women, married young women and children at Lake Kushaqua in the Adirondack mountains. The Erie County (N. Y.) Almhouse is to build a $50,000 hospital for their consumptive inmates. Bellevue Hospital has established a ward to accommodate 200 patients.

A bill was introduced in the legislature of Massachusetts to establish a second state institution in the mountains, to accommodate the patients who apply for treatment.

A bill was introduced January 2 in the legislature of Minnesota providing $150,000 for the erection and $50,000 for the maintenance of a state sanatorium for consumptives.

California has appointed a committee to investigate the feasibility of establishing a state institution in the southern part of California.

Texas has a farm for consumptives two miles from the Huntville penitentiary. Men who went to the farm in the last stages of the disease are now hearty and stout, and evince no evidence of the disease. The plantation is self-supporting through the labor of the invalids.

Louisiana is to establish a consumptive camp at Covington, 50 acres of land having been procured for that purpose. Michigan is considering a bill for the establishment of a state hospital. New Jersey is urging an appropriation for the same purpose. The Pennsylvania legislature is asked for $60,000 to establish free homes for consumptives near White Haven. Boston has four hospitals for the treatment of consumptives, and is about to erect another to cost $80,000. New Hampshire is about to investigate the question.

The government sanatorium at Fort Stanton, N. M., is a success. It has been in operation 18 months, and has treated 92 patients, 12 of whom were discharged as recovered, 15 improved, and 11 died. The cases received were nearly all advanced.

Look over this list and you will perceive that these proposed institutions will be located in different sections of the country, many of which can lay no claim to advantages as health resorts. Cast your eye over the land between the Appalachian range and the Rocky mountains and you can pick out hundreds of places which present advantageous points for the location of sanatoria. Minnesota has a dry bracing air which sustains its reputation for healing it gained many years ago; the region of the great lakes proves by statistics that consumptives may live there; the pines of Wisconsin offer healing balms to the consumptive, and the Ozark mountains, hitherto neglected, are readily available for the invalids of Chicago, St. Louis, Indianapolis, and other great cities in the Mississippi valley. If you go further south into Kansas, approaching the Rocky mountain chain, you secure the desired altitude, and for the equable sedative climate you go down into Texas.

For one, I would answer the question of the curability of consumption in the middle states in the affirmative; hence, I would urge the physicians who are present from these states to return to their homes and agitate for the erection of state sanatoria, or private sanatoria if the state will not give a helping hand. I am sorry to say my own state, Illinois, which stands fifth in the mortality list, refused to take high rank in providing a state sanatorium. The excuse is, no money, but a glance at the appropriation list will tell where the money went.

THE BIOLOGIC TEST FOR SEMEN.

C. G. FARNUM, M.D.

(From the Pathological Laboratory of Rush Medical College.)

CHICAGO.

In this work I have applied to semen the biologic test for blood. This test is based upon the fact that when certain substances, such as bacterial filtrates, peptone, milk, egg albumin, albuminous urine, blood serum, etc., are injected into animals at intervals for a period of time they produce in the blood of the animals substances which form specific precipitates with the substances injected.

Rabbits have been injected intraperitoneally with either semen or testicular emulsions of the dog, bull or man, at intervals of from two to six days and in quantities of from 5 to 10 c.c. at each injection. They received from five to eight injections each. The blood serum for the tests was diluted from twelve to eighty times and the semen or testicular emulsions from four to twenty-five times in physiologic salt solution.

The blood serum of the rabbits injected with dog semen and with emulsion of dog's testicle gives distinct precipitates with clear filtrates of these substances, but no precipitate occurs with human semen or with the emulsion of bull's testicle. Normal rabbit's serum and the emulsion of dog's testicle give no reactions. The amniotic fluid from one of the rabbits gives the same reactions as her blood serum. I have not been able as yet to determine whether the serum of these rabbits gives precipitates with dog's serum; nor have I tested the agglutinating power on dog's spermatozoa of the serum of the treated rabbits.

The serum from a rabbit treated with emulsion of bull's testicle gives a precipitate both with the emulsion used for injection and with a salt solution emulsion of spermatozoa taken from the epididymis. No precipitate occurs with human semen, nor with the emulsion of dog's testicle, nor with an emulsion of goat spermatozoa.

The serum of the rabbit treated with human semen gives a distinct reaction with both recent and old emulsions of human semen in salt solution; also with human semen which had been dried and preserved thirty-four days on filter paper and on cloth, which were soaked in salt solution and the fluid carefully filtered. But with emulsions of bull, of dog and of goat testicles no reaction takes place. With human blood serum, human semen gives no precipitate.

While the experiments should be extended much further and modified in various ways, I think it safe to conclude that blood sera of animals treated with different semens and testicular emulsions contain precipitins, which probably are specific.

That the substance which gives rise to the precipitin is contained in the semen itself and not in the blood serum or its direct derivatives seems probable from the absence of precipitate in human serum to which is added the serum of rabbit treated with human semen. Here there is also room for much further experimentation.

Since dried semen of considerable age (34 days) gives the reaction it would seem that the test may be of practical value for the detection of the nature of suspected seminal spots.

Havana's Sanitary Condition.—During the month of November there were no cases and no deaths from yellow fever. The city has had no such record for any preceding November since 1762.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, DECEMBER 28, 1901.

The large amount of space occupied by the Index in this issue necessitates the entire omission of some of the departments, and a reduction in the amount of space devoted to others.

THE INDEX OF AMERICAN MEDICAL LITERATURE.

There is one part of the Index printed in this issue of The Journal to which we desire to call attention. It has been a feature of the last five volumes, and yet it has been lost to many of our readers, because its nature has not been known. The feature referred to is the Index to American Medical Literature, commencing on page 1756. This is, in truth, an "Index Medicus" of American Medical Literature, covering, as it does, practically all the original articles in all the reputable medical journals of this country and Canada, including those which appeared in The Journal. Under "Index of Authors" is given the name of every author who has published a paper in the journals during the six months, giving references which include the titles of papers and where published. The Index to the titles is crossed sufficiently to enable one to look up any subject.

This phase of our index takes a large amount of labor and we do not hesitate to call attention to it prominently, believing that this effort on our part needs only to be known to be appreciated. The need of such an index is increasing every year as American medical contributions become more numerous and more valuable. In future years this series of indexes with the volumes of The Journal will be the readiest and probably the only means of convenient general reference for the student and worker in the medical literature of this country for the period they cover.

The Index of American Medical Literature will be issued separately, and bound, with the titles as these were printed each week in The Journal. It will make a ready reference to authors, titles and subjects comparatively easy. This will be supplied to members and subscribers at 10 cents, and to others at 25 cents.

ADRENAL DIABETES.

It has long been known that each tissue selects from the blood or serum brought to it the pabulum necessary for its existence and activity, and gives back the products of its metabolic metamorphosis. It is, however, only within quite a recent period that special importance has been attached to the so-called internal secretions, namely, the hypothetic products of the ductless glands, such as the thyroid, the adrenal, the spleen. The question has further arisen whether even organs provided with excretory ducts may not generate internal, in addition to their external, secretions. As a result of the interest that the subject has aroused and the important problems that are bound up with it, its study has naturally received a generous share of attention.

It is currently believed that myxedema is due to the suppression of the internal secretion of the thyroid gland, and that the symptom-complex known as Addison's disease is due to suppression of the internal secretion of the adrenal glands. Further, it has been suggested that in addition to the active and important digestive products secreted by the pancreas, this organ produces an internal secretion, suppression of which gives rise to diabetes.

Quite recently F. Blum[1] has recorded observations that go to show that the adrenal gland may also be in some way related to diabetes. It was found that these glands contain a substance that, introduced into the circulation, caused glycosuria. Administration by the mouth of an extract, or of the substance, of the gland did not materially affect nitrogenous balance, and was never followed by the appearance of sugar in the urine. On the other hand, sugar appeared in the urine almost invariably after introduction subcutaneously of adrenal extract, provided the amounts employed were not too small, even when the food was free from carbohydrates. In these observations, the adrenal gland of the sheep was used principally; in some instances, that of the calf; in one, that of the dog; and in one, that of a human being. The extract was prepared by the addition of 5 c.c. of water to one finely divided gland, and exposure for several hours at a temperature of 0 C. This was rendered sterile by filtration or by heating on successive days. The filtered extract proved the more potent. The extract was injected subcutaneously, in order, among other things, to avoid the marked increase of blood pressure induced by intravenous injection. Twenty-five animals, 22 dogs and 3 hares, were submitted to observation. In each instance, the urine previously had repeatedly been found free from sugar. In two uncontaminated urine could not be obtained after the injection and one animal died; but in all the others sugar appeared in the urine for a varying period of time.

The results recorded are so constant that there would seem to be no doubt of the power of the adrenal gland to cause the presence of sugar in the urine. This, it is thought, is due to a toxic effect upon one or several organs concerned in carbohydrate metabolism. The hypothesis is suggested that the adrenal glands perform an antidotal or antitoxic function, neutralizing or eliminating certain poisonous substances that find their way into the circulation. Loss of this function will result

1. Deutsches Archiv f. Klin. Med., 71 B., 2 und 3. H., p. 146.

in adrenal cachexia or Addison's disease, while its partial performance gives rise to diabetes—in the same way as it is supposed that loss of the function of the thyroid gland is followed by tetany, myxedema, cretinism, etc., and mere insufficiency of the gland is attended with the symptoms of thyroidism and exophthalmic goiter. If the numerous investigations and the accumulated knowledge upon the subject of diabetes teach anything, it is that we have to deal with derangement of a somewhat complex process, the elimination of certain factors of which results in metabolic disturbances manifested by the appearance of sugar in the urine. In this way we may have glycosuria of central, of alimentary, of hepatic, of pancreatic, of adrenal origin, and possibly there may be other types of the disorder.

DERMOID CYSTS AND TERATOMAS OF THE MEDIASTINUM.

Dermoid cysts and teratomas constitute a most interesting subject. Common in the ovary and comparatively infrequent elsewhere, their genesis has always been an inviting problem which has led to the formulation of many theories. The number of cases described in the anterior mediastinum since Gordon's first case, in 1827, is now quite considerable. Thus Mandlebaum[1] collected 37 cases, and more recently Christian[2] brings the number up to 40, each describing a case of his own. Christian submits an analysis of the collected cases. The majority occurred in young adult life. Among other symptoms than those of pressure the coughing up of hair is very noteworthy, being of pathognomonic significance; it occurred in 8 cases. The growth most frequently develops in the upper part of the anterior mediastinum, between the sternum and the great vessels. The size has varied from that of a "pigeon's egg to a tumor larger than a child's head." From their structure the tumors may be divided into, 1, simple dermoids (cysts of ectodermal origin with some tissue from mesoderm); 2, more complicated growths of the class of teratoma proper, and 3, tumors of either of these two kinds that have become the seat of malignant transformation. Mandlebaum's case contained vesicles like those in the thyroid. Only two cases of real teratomas have been described, and three of malignant transformation. Two of eight cases subjected to operative treatment have been cured; of course, this form of treatment is the only one that would seem to offer any hope in the face of a constantly-growing tumor.

Earlier writers attributed dermoids and teratomas to abnormal pregnancies inflicted as punishment. There is a far cry from the period of that notion to the present view that dermoid cysts arise from misplaced fetal tissue. In the neck there is great complexity in the developmental changes which can not but favor misplacement of parts of the germinal layers. In several cases the structure of the growths shows distinct generic relation with the thyroid and the thymus. Hence the tendency is to refer the majority to a branchiogenic origin, downward migration giving the tumor its final position. But some of the dermoids may result from misplacement of the germinal layers during the closure of the anterior chest wall. The teratomas proper may be explained according to the general theories advanced in regard to such formations,[3] or it is possible, as Christian suggests, that they develop from ordinary misplacements including all three germ layers.

BLUE URINE.

The normal amber color and transparency of urine may be changed as a result of alteration in concentration, in temperature, and in chemical constitution. The color may, further, be profoundly influenced by the ingestion of certain substances, such as rhubarb, santonin, gamboge and methylene-blue, and from the presence of certain morbid conditions, such as melanotic new growths, pernicious anemia and intestinal obstruction. Indican is by no means a rare constituent of urine, but indigo, in amounts sufficient to give the urine a distinct bluish coloration, is not so often observed. A case of this latter kind has recently been reported by A. McPhedran and William Goldie.[1] The patient was a man, 24 years old, of sedentary habits and sallow complexion, who complained of weakness and heaviness of the lower extremities, palpitation of the heart, dull headache, and an inaptitude for work. He smoked heavily and ate irregularly and rapidly. The bowels were regular. The stomach was displaced slightly downward, but its secretory and motor functions were well performed. The urine, however, was found to be turbid and bluish-green in color, and chemical tests yielded the reactions of indigo. This substance has been observed in the urine in connection with profound intestinal disorder, such as occurs, for instance, in cases of Asiatic cholera and typhoid fever. It is believed to be derived from indol, which is a product of albuminoid putrefaction, and is transformed, principally in the liver, into indoxyl, and this in turn into potassium indoxyl sulphate. The latter, generally after being voided and standing, is converted into indigo, though sometimes the decomposition takes place in the bladder. The almost constant presence of bacteria in the urine under the circumstances under consideration raises the suggestion whether they may not possibly have something to do with the chemical changes that result in the production of the pigment.

Fundamental Principles of the Pathogenesis of General Infections.—Omeltchenko publishes in the Russian *Botkine's Gazette*, No. 30, an account of his study of the growth of various microbes on a number of culture media made of macerations of the different organs of the body. He found that certain microbes have an unmistakable special affinity for certain organs and thrive on them to the exclusion of others. It is evident that the infection from these germs must develop along the lines of these affinities. He publishes a set of tables showing the application of this principle to the pathogenesis and course of general infections.

Medical News.

NEW YORK.

Rochester City Hospital Donation.—The Rochester City Hospital expects to receive about $9000, the proceeds of entertainments recently given for its benefit.

Transfer of Insane.—The State Commission in Lunacy has decided to relieve the overcrowded condition at Utica State Hospital by transferring 30 patients to the Hudson River State Hospital, Poughkeepsie, 30 to Willard State Hospital, Seneca Lake, and the remainder to the St. Lawrence State Hospital, Ogdensburg. The transfer has also been ordered of 20 patients from Buffalo to Seneca Lake and of 100 women from Buffalo and 100 from Poughkeepsie Hospital to the Manhattan State Hospital, New York City.

"Polypaths" Raided.—The board of censors of the Erie County Medical Society has caused the arrest of A. J. Wiechers, who ran a "magnetic healing" establishment in Buffalo, known as Wiechers' Polypathic Institute. In his affidavit, a policeman detailed to obtain evidence, states that when he entered the establishment and asked to see the doctor he was approached by the "Boy Wonder," who collected from him a fee of $1. He was then told that he had some pulmonary trouble, to effect a permanent cure of which would cost him $25.

The re-organization of the Pathological Institute of the New York State Hospitals, made necessary by the resignation of the former director. Dr. Ira Van Gieson, early last summer, has been proceeding slowly. The Civil Service Commission, after an examination of prospective candidates held December 7, have certified to the eligibility of Dr. Adolph Meyer, of the State Hospital and Clark University, Worcester, Mass., and he has been appointed by the Lunacy Commission to fill the position of Director of the Institute.

New York City.

German Hospital Annex Dedicated.—The annex to the German Hospital, 77th street and Lexington avenue, was formally dedicated December 7.

Janeway Portrait Presented.—A portrait in oil of Dr. Edward G. Janeway was given to the Academy of Medicine at the annual anniversary meeting of the institution, December 5.

PENNSYLVANIA.

Hospital Moved.—The East End Hospital, Pittsburg, has moved into its new quarters recently purchased for $100,000. The hospital now has accommodation for 28 patients. On the site at Silver Lake Grove, the new hospital will be erected at a cost of $500,000.

Free Hospital for Poor Consumptives.—The institution is now caring for about 75 patients. Of there 55 are distributed among the German, University, St. Agnes', St. Mary's and Rush hospitals, Philadelphia, and the other 20 are in camp near White Haven, Luzerne County, where the patients have made most gratifying progress.

New Hospital Buildings.—Earth has been broken for three new buildings on the grounds of the Philadelphia Hospital, which will cost when completed, $80,000. They are to be known as the Maternity Home, the Children's Hospital and the Hospital for the Treatment of Contagious and Venereal Diseases, and will be ready to receive patients in about three months.

Medical Staff Re-elected.—The medical staff of the Philadelphia Hospital was re-elected by the Board of Charities and Corrections, December 11. Dr. George M. Boyd was appointed to fill the vacancy on the obstetrical staff caused by the resignation of Dr. George I. McKelway. The resignations of Dr. ment, and of Dr. R. D. Burke, outdoor physician, were received.

WISCONSIN.

The Milwaukee Post-Graduate Medical School and Polyclinic has been incorporated with a capital stock of $25,000 by Drs. William H. Earles, Walter H. Neilson and Warren B. Hill.

New Medical Examiners.—The governor has appointed Drs. John R. Currens, Two Rivers; J. V. Stevens, Jefferson, and F. A. Forsbeck, Milwaukee, members of the State Board of Medical Examiners, representing the regular, eclectic and homeopathic schools respectively.

Fire in Sanatorium.—Fire in the barn of St. Mary's sanitorium, Milwaukee, December 8, for a time imperiled the lives of the 28 inmates of that institution. The main building was filled with smoke and the panic-stricken patients were taken out with difficulty by the firemen. All were rescued safely.

Osteopathic Decision.—The case against Miss Belle Phillip, of Chicago, who was arrested at Manitowoc, upon a warrant sworn out by Dr. John R. Currens, president of the State Board of Medical Examiners, for advertising treatment by osteopathy, without a license, was dismissed, December 11. Her attorney moved a dismissal upon the ground that there was no infringement of the law and because the law itself was ineffective in not providing a penalty, the section providing for a penalty relating to the practice of medicine and surgery alone.

Waukesha Springs Sanatorium Burns.—The Waukesha Springs Sanitorium, a new building constructed at a cost of $50,000, of which Dr. James H. McBride was president, was almost destroyed, December 3. At the time of the fire, the building had been practically finished, although some of the contractors' work had not yet been accepted, and the second and third floors were ready for use. It was expected that the patients would be moved to the new building by the first of the new year. The loss will probably be about $45,000. Of this amount $30,000 is covered by insurance.

Smallpox.—The public schools of New Cassel and Campbellsport have been closed on account of the disease.——Lumbermen at Niagara refuse to observe quarantine and a great increase of the disease is feared.——The illness of a telephone operator has caused the quarantine of the exchange at Green Bay.——In Antigo there are 6 cases; in Akley, 1 case; in Neba, 15 cases; in Peck, 8 cases; in Elso, 5 cases, and in Evergreen, 7 cases.——Green Bay has 40 cases.——The disease has appeared in nearly every township of Houston County.——Tomah reports 31 cases.——At Merrill 19 cases have occurred.——Two cases have been discovered in Racine.——Big Spring has 15 cases.——At Fond du Lac a case has occurred in the home of the health commissioner.——The epidemic at Odanah has apparently been stamped out. There were 165 cases with 3 deaths. There are now only 3 cases on the Indian reservation, one at Lac du Flambeau, and two at Floodwood.——At Sturgeon Bay, 16 cases are said to exist, and 26 cases at Sevastopol.——At Kaukauna, 4 families have been quarantined.

Correspondence.

Needle in Rectal Wall.

COCHRANTON, PA., Dec. 10, 1901.

To the Editor:—On the evening of November 20, Mr. T. M. M. came into my office complaining of what he thought was of hemorrhoidal nature, suffering pain and uneasiness in lower part of the rectum. I made an examination and could fine nothing of that character. I treated him for about two days, and being no better, but rather worse, I dilated the anus and could see only a very small ulcerated spot on the wall of the rectum. On further examination with my finger, I found at about one and one-half inches up in the rectum, part of a large sewing needle, with the point down. I could feel the click under my finger nail. I then took a pair of forceps and brought the point through the rectal wall and extracted a large-sized needle. The mischief already done by the needle culminated in a large abscess, which I opened a few days later, externally, about one inch to the left of the anus. I washed out the cavity with antiseptic solution and in a short time the sac was obliterated and there is as yet no appearance of fistula.

I consider myself fortunate to have located the trouble, removed it, and have a favorable termination. The question arises: How did the needle get there, as he had no recollection of any experience with needles? His mother thinks it must have been there from childhood.

Yours respectfully, W. C. BRITTAIN, M.D.

Anesthesia of the Membrana Tympani.

MEMPHIS, TENN., Dec. 11, 1901.

To the Editor:—In the *Philadelphia Medical Journal* for October 5, 1901, page 574, Dr. Jack of Boston makes the following statement in speaking of acute otitis media: "I have little faith in the anesthetic properties of local applications of cocain on the inflamed ear, nor have I found any drug satisfactory in lessening the pain of an incision."

In THE JOURNAL A. M. A., for April 27, 1901, I published a letter on the subject of an anesthetic mixture for use on the drum membrane. Since its publication I have received numerous inquiries concerning the mixture and its use, an evidence that the subject is one of much interest, while favorable reports from some of my colleagues and the continued satisfaction which it has given me have further confirmed me in my opinion as to its value. Dr. Jack's statement leads me to make mention of it again. The mixture is composed of equal parts of cocain hydrochlorate, menthol and carbolic acid. The substances combine to form a slightly turbid liquid of a thin syrupy consistence, permitting its application with a cotton-tipped applicator. If this application is made with due gentleness there is no difficulty in using it on the drum even in little children. The canal should be first rendered aseptic with a warm bichlorid solution, which serves the additional purpose of removing particles of cerumen, desquamated epithelium, etc., which might obstruct the view of the deeper parts. After thoroughly drying the canal with a cotton-wrapped applicator, the anesthetic mixture is applied on another applicator similarly prepared with a very small amount of cotton, so that its contact with the drum can be watched and made to a small area. I usually make two or three applications to the posterior portion of the drum where the incision is to be made. There is a slight whitening of the parts touched, just enough to enable one to tell the extent of the anesthetized area. In a minute or two the drum is completely anesthetized and can be incised without pain. I have used the method a good many times on both inflamed and uninflamed drums, and in not one instance has it failed. Adults have frequently assured me that they felt no pain, and as frequently I have performed the operation in children without their ever knowing that anything had been done except the introduction of an applicator. Sometimes in nervous children who will not permit you to touch the aching ear it is necessary to give a general anesthetic, but this is on account of nervousness and not pain.

This mixture is certainly not so caustic as pure carbolic acid, while probably more anesthetic. I am inclined to believe that the carbolic acid is the most active ingredient and cocain the least active, judging from the action of these drugs under other forms in this locality. I agree with Dr. Jack as to the total absence of effect produced by cocain alone on the drum.

The points I have mentioned are largely those suggested by inquiries made of me concerning the preparation and use of this mixture. This mixture is not original with me, but was first published by Bonain in the *Rev. Hebd. de Laryng.*, June 17, 1899.

The recent report of alarming symptoms from the use of the anilin oil mixture used by English surgeons (A. A. Gray, *The Lancet*, April 21, 1900) for producing anesthesia of the drum, is another reason for my wishing to again call attention to Bonain's mixture, which is free from any deleterious effects.

There is a point in Dr. Jack's paper on which I would like some information. He speaks of emptying the middle ear after paracentesis, and subsequently by inflation. I am under the impression that this is a way productive of mastoid complications, and in several cases I believe I have seen them brought about by this practice. It is a very difficult point to prove, but the development of mastoid symptoms in cases where I was using inflation has somehow so impressed me with the fear that it might have been caused by the procedure, that it has lead me to abandon inflation and rely on aspiration and gauze drainage for emptying the middle ear, even in chronic suppurative cases.

Very truly,

E. C. ELLETT, M.D.

Book Notices.

A MANUAL OF THE PRACTICE OF MEDICINE. By George Roe Lockwood, M.D., Professor of Practice in Woman's Medical College of New York Infirmary. Second Edition, Revised and Enlarged. With 79 Illustrations and 20 Full-page Plates. Cloth. Pp. 847. Price, $4.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

This volume consists of a thorough revision of the first edition, with many portions rewritten and new subjects added. The descriptions of disease are plain and concise and the student in many cases gets a clearer and more enduring conception, for instance of broncho-pneumonia, than in many of the larger works. The work is well supplied with fever charts.

CHIMICA CLINICA. Dott. Raffaele Supino, Assistente alla Clinica Medical Generale di Pisa. Cloth. Pp. 198. Milano: Ulrico Hoepli, 1902.

This is a very convenient little work on clinical chemistry covering the technique of qualitative analysis more particularly, according to various methods and covering also examinations of the principal fluids and secretions of the body. It also gives tests for various drugs and would be a convenient addition to the library of any practical physician who is acquainted with the language in which it is written.

INDUCTION COILS. How to Make, Use and Repair Them, Including Ruhmkorff, Tesla, and Medical Coils, Roentgen Radiography, Wireless Telegraphy, and Practical Information on Primary and Secondary Battery. By H. S. Norrie, Second Edition, Revised and Much Enlarged. Cloth. Pp. 269. Price, $1.00. New York: Spon and Chamberlain. 1901.

This little work has been enlarged and brought up to the latest American practice in accordance with the increasing interest given to this subject. It has 79 illustrations.

ESSENTIALS OF OBSTETRICS. By Charles Jewett, A.M., M.D., Sc.D., Professor of Obstetrics and Gynecology in the Long Island College Hospital. Assisted by Harold F. Jewett, M.D. Second Edition. Illustrated by 80 Woodcuts and 5 Colored Plates. Cloth. Pp. 386. Price, $2.25. New York and Philadelphia: Lea Brothers & Co. 1901.

This volume represents a thorough revision of the first edition. The author has endeavored to make plain to the student the essential facts of obstetrics, and has admirably succeeded in doing so in the chapters on the physiology and mechanism of labor. Several pages are devoted to artificial feeding.

DISEASES OF THE DIGESTIVE ORGANS in Infancy and Childhood, with Chapters on the Diet and General Management of Children, and Massage in Pediatrics. By Louis Starr, M.D., Late Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania. Third Edition; Rewritten and Enlarged. Illustrated. Cloth. Pp. 448. Price, $3.00. Philadelphia: P. Blakiston's Son & Co. 1901.

The appearance of a new edition of Starr's work on digestive diseases in infancy and childhood will be welcomed by the profession. The author has revised his work to bring it up as nearly as possible to the advances that have been made during the last ten years. The most important additions are the sections on simple atrophy, infantile scurvy, rickets, lithemia, infectious follicular tonsillitis, naso-pharyngeal adenoid hypertrophy, proctitis and appendicitis. The milk modification question, which is so much to the fore at the present time, is also thoroughly treated.

Miscellany.

Physician Wanted.—A recent number of the *New York Herald* devotes half a column to an experience meeting of one of the local organizations which derives a large annual income from its boasted facilities for healing by prayer. The head financier was asked what was the proper course to pursue when a patient under the care of one of his followers died, in order to escape the embarrassment imposed by the Board of Health in refusing to permit burial without a certificate of death. The *Herald* quotes him as follows: "The alliance has always managed to avoid embarrassments of this kind. We must recognize the law of the state. What I advise is, that when a case is critical we should be in touch with a *reasonable, considerate Christian* physician, [italics ours] so that we can call him in to give this needed certificate. Thus we shall be able to respect the law and yet trust the Lord." We do not recall amongst our acquaintance a single physician "reasonable" enough to commit infor-

mal perjury on request, or "considerate" enough to sympathize with an impostor menaced by the recoil of his own imposition. We take it, however, that the christianity specified is of the garden variety, which passes current in such circles, and should be well within the compass of any one qualified in the first two particulars. It has occurred to us, nevertheless, that there may be some physician, though we shall be disappointed if we number him among our regular readers, who has had his lucrative income threatened and his select clientèle scattered by the recent activities of the Committee of Fifteen, and to him we are sure such an appeal will not be made in vain.—*N. Y. State Jour. Med.*

The Study of the History of Medicine.—An International Congress of Historical Sciences is to be held in Rome about the middle of April, 1902. A section has been allotted to the history of medicine and ancillary sciences. The President of the Section is Professor Piero Giacosa, who has issued a circular inviting those interested in such studies to attend "in a numerous and compact body, to justify the honor paid to this branch of study which has been placed on a level with others, and to fraternize with each other and with their colleagues of the other sections." The Section of the History of the Mathematical, Physical, and Natural Sciences, the President of which is Professor V. Cerutti, will hold some meetings in conjunction with the Medico-Historical Section for the discussion of subjects belonging to both fields of research. The German Society for the Study of the History of Medicine and the Natural Sciences which was founded at the time of the annual meeting of the Association of Scientists and Medical Practitioners, held at Hamburg last September, has already a membership of sixty, including Germans, Austrians, Hungarians, and Swiss. The Society has undertaken the issue of a periodical review of all publications on the history of the pure sciences and medicine. The first number of this review will appear in January, 1902. The President of the Society is Dr. Karl Sudhoff, of Düsseldorf, the well-known authority on Paracelsus; the vice-president is Dr. Emil Wohlwill, of Hamburg. Among the members are Professor Kahlbaum, of Basel, and Dr. H. A. Peypers, of Amsterdam, the editor of *Janus*.—*Brit. Med. Journal*, Nov. 30, 1901.

Blood Examination.—The following method for the preparation of specimens for the examination of blood is given by Dr. W. L. Braddon, of the Malay Peninsula: The mounts may be made either between two square cover-glasses, or a square cover-glass and a regular size slide. The covers and slides are first sterilized by a method recommended by Parker and Howard; viz., drop, one by one, into a 10 per cent. solution of chromic acid, contained in an enameled iron dish, and boil for twenty minutes. They are then poured, altogether, into a shallow basin, and washed with ordinary tap water until no trace of the yellow color of chromic acid remains. The water is next poured off, and the slips are covered with rectified spirit. After this they are washed in absolute alcohol, and handled with clean forceps. If two cover-glasses are used for the mount, they are accurately superposed and firmly pressed together. An edging of vaselin, if for temporary purposes, or cement if for permanent purposes, is laid over all the edges, except one, and a very small portion of that edge which is opposite the uncemented one. A drop of blood is touched with the free edge of the paired cover-glasses, whereupon the blood enters between the glasses in an exceedingly thin film, the corpuscles being spread out with beautiful uniformity, and having suffered a minimum amount of change from exposure to air and none at all from handling or pressure. When the blood film has entered, the free edges may be completely closed, and the examination made. If slide and cover-glass are used the latter is placed on the slide in such a position that one of its edges exactly coincides with that of the slide. It is then firmly pressed, and sealed with vaselin or cement, as when two cover-glasses are used, and the subsequent course pursued as with covers. By this method a number of mounts may be made and stored in a suitable air-tight bottle, and thus be always ready for use. Fresh blood keeps well under these circumstances. No special skill is required for the making of first-class blood film. This method has been carefully tested, and it was found necessary to put the smallest possible amount of cement between the covers before edging them outside, otherwise the cement had a tendency to run in.—*Knowledge*.

The County Medical Society.—One of the fundamental principles of the reorganization of the American Medical Association makes the county medical society, or the district medical society where there is no county society, the unit of membership. Membership in the local society is the first requisite for membership in the American Medical Association. This is as it should be, although owing to the local conditions it is likely to cause confusion in some counties where, because of the disaffection of the local profession, there exist rival medical societies in the same county. In order that the great professional machine which is contemplated, may be complete in all its parts, and may work smoothly, two great principles must be recognized in every county; first, there can be but one official society in each county recognized as in affiliation with the Association, and second, every reputable non-sectarian physician can demand as his legal right, membership in that society, unless it can be shown after official investigation, in the course of which the candidate may, if he desires, be represented by counsel, that the physician in question has been guilty of unprofessional conduct and is for that reason unfit for membership in the American Medical Association. In other words, personal feeling, individual likes or dislikes, must have no weight in the elections for membership in the County Society. In certain parts of the country professional jealousies and misunderstandings and personal feuds have interfered with the smooth conduct of the county societies and in not a few counties these have resulted in the division of the local profession into two rival factions, each claiming to be the representative body. This must be done away with and the local conditions readjusted. This will undoubtedly bring about a general clearing of the professional atmosphere and in many cases old misunderstandings will be explained or forgotten and harmony will be brought about. There is no objection to special societies and medical clubs and academies of medicine, which may be as exclusive as they desire so long as the county society stands alone as the one official representative professional body, enrolling in its membership every reputable physician in the county. If the suggestion made by the committee on reorganization is adopted, as it should be, every member of the County Society would become without further action on his part a member of the state society and the dues of the state society will be paid out of the fund of the county societies, which with its largely increased membership would be amply able to pay them. We are happy to state that in Minnesota professional affairs are extremely harmonious. So far as we are aware there are in this state no rival county societies, although there are a number of counties where it will probably be necessary to organize societies. . . . . No one who has given thought to the subject can fail to realize the great benefits to our profession as a whole as well as to its individual members, which are sure to result from the harmonious working out of this grand scheme of professional organization.—*St. Paul Medical Journal*, December.

AMERICAN.

1. **Surgical Treatment of Cancer.**—Abbe, in his article, holds there is too little attention given to thorough extirpation, giving the widest possible berth to apparent growths in operation. He believes that what we call a skilful operation to extirpate cancer in any part of the body requires all the coolness and courage that a man can bring to bear within the hour or two of concentrated work. A radical cure, he holds, can occasionally be hoped for by extirpation and surgery has so far mitigated suffering and lengthened life that we may consider that we have made a long stride toward its mastery. He reports a number of cases of apparent cures that have been obtained by operation.

2. **Rheumatism and Throat Inflammation.**—The connections between rheumatism and soreness of the throat are reviewed by Cheatham, who summarizes the present state of our knowledge of the relation of tonsillar affections to rheumatism as follows: "1. It is undoubted that a certain number of cases of acute rheumatism are preceded by an angina in a proportion varying from 30 to 80 per cent. 2. Both rheumatism and angina have many etiological points in common—season of year, cold, wet, fatigue, depression, vitiated air, etc. 3. The connection of angina and rheumatism, though undoubted in a number of cases, is not yet clearly established. 4. The tonsil may be the port of entry of the rheumatic virus, al-

though the naked-eye appearance of the throat gives no indication of its being affected. 5. The particular affection of the throat which is associated with rheumatism is not yet established. Apparently it is not peritonsillar abscess (quinsy). 6. Peritonsillar inflammation does not appear to be arrested by the administration of anti-rheumatic remedies. Many cases of parenchymatous and lacunar tonsillitis, on the contrary, are considerably benefited by the administration of salicin or salicylate of sodium. That this action proves the rheumatic nature of the disease can not yet be accepted. The question requires further research in two directions: One in differentiating the various forms of angina, and settling the one which is associated with rheumatism; the other in further research to discover the true nature of rheumatism." He believes that chronic rheumatism causes frequent attacks of inflammation of the tonsils, pharynx and larynx; that acute exacerbations in chronic and acute rheumatism are frequently ushered in or preceded by an acute tonsillitis and that we have following such all the heart, joint and other lesions occurring after any rheumatic affection.

3. **Rheumatism.**—After noticing the theories of the bacteriologic and other origins of rheumatism, Thelberg says the probably correct definition is, that rheumatism is a general disease of bacteriologic origin characterized by special articular and cardiac manifestations and contracted by persons whose blood on account of perverted metabolism is at specially low alkalinity and immunizing power. His treatment has been almost exclusively on the line of digestion and general hygiene, and he has found all rheumatics to be chronic dyspeptics of some form or other. He divides his patients into two classes. The first are spare nervous men, or especially women, who often suffer from headache, lack of appetite, distress after eating, constipation; they are extremely light eaters, but great tea and coffee drinkers; they allow themselves too little exercise and exposure to fresh air and sunlight, rarely if ever cold baths, hot bath almost always in excess or not at all. The second type is the ruddy fat man or woman, with flabby, distended abdomen, sedentary habits, hearty eaters and drinkers, with chronic gastro-intestinal catarrh and a general condition below normal, notwithstanding the deceptive appearance. He treats these largely with dietetic measures; calomel, sponge baths, salines, morphin hypodermically, ice to the affected joints, and if necessary, to the precordia, cold sponging followed if necessary by some antipyretic, together with hygienic and hydrotherapeutic measures generally, have proven effective, and certainly more so than the salicylates.

6. **The Urethroscope.**—Otis describes his most recent modification of this instrument and claims for its advantages, illumination of field such as is not found in any other type. It gives the entire field of the tube used, offers no obstruction to the use of applicators, and at the same time nothing is inserted into the urethra which can not be rendered thoroughly aseptic by boiling. It is simple in construction, strong and inexpensive, and fulfills all the indications of a good, practical, working instrument.

9. **Rectocolitis.**—Beach concludes his article with the following: 1. Rectocolitis is a condition of the rectum and colon of varying degrees of inflammation. 2. A knowledge of the anatomic bearings of the rectum and colon is necessary to understand the symptoms and reflexes. 3. The symptoms are local and systemic. 4. Rectocolitis may be catarrhal or ulcerative. 5. It may be acute or chronic. 6. When dependent upon polypus, hemorrhoids, fistula, etc., the cure depends on their removal. 7. Chronic rectocolitis due to altered secretions, anemia, and congenital narrowing of the sigmoid strait, is difficult to cure.

10. **Pneumonia.**—Twelve cases are reported by Sears in which the antipneumococcus serum was used, and while the author does not maintain that the serum produced distinct benefit there were no ill-effects beyond what might occur from the use of diphtheria antitoxin. Considering the unsatisfactory nature of the cases he believes the facts justify further trial of this form of treatment.

13. **Tumors of the Breast.**—The operation used in early cases by Gleason is what he calls the Banks-Halsted method, differing from the regular Halsted operation in the deep undercutting of the skin and retention of the pectoral muscle and the glands of the posterior triangle, unless the nodes of the axilla are infected. This is the method employed in the early cases. In all advanced cases the operation is much more extensive. With non-operative cases the palliative treatment seems to be the only thing to be relied upon. The three troublesome symptoms are hemorrhage, foul discharge and pain. The use of fluid extract of ergot internally and ergotin hypodermically will control the hemorrhage. Deodorization may be obtained with an aseptic such as carbolic acid 1 to 40, creolin or lysol 2 per cent. Opium in the form of the tincture is far the best remedy for pain, and may be administered by rectum or mouth, even if the dose becomes enormous. It plainly becomes one's duty in these extreme cases to relieve the inevitable pain; he insists on the importance of early diagnosis.

14. **Massage.**—Graham has tried massage in a number of cases of paralyses, and says that in the absence of severe pain, obstinate contraction or tonic spasms, this procedure is useful in improving the circulation, temperature and comfort of the parts affected. In cases of paralysis of cerebral origin, where recovery has followed under manipulation, he had previously supposed that the central disturbance had entirely passed away and that the force of habit was the main factor that continued the external manifestations of inaction; and that massage would have served a useful purpose for diagnosis as well as treatment. The recent experimentation and opinions of Zabludowski and others taught him that it is possible to educate other portions of the brain to take the place of the injured ones controlling the movement of the paralyzed parts, and we need no longer regard paralysis as hopeless as was formerly the case. He reports cases which seem to point out to him this truth.

15. **Laryngeal Paralyses.**—Gleitsmann begins with a description of the anatomy and physiology of the larynx with special reference to abductor paralysis and the tendency to it as pointed out by Semon. The different forms and modes of occurrence of the abductor paralyses are noted. The adductor paralyses are not noticed at such length and their pathologic importance is considered decidedly inferior.

16. **Quarantine.**—Foxworthy in his report shows the faulty methods of quarantine that are used throughout the world and calls attention to the need of a conference of medical men from all civilized nations to consider it. He thinks it would be a great advantage if such a meeting were held in the United States and if some such step is not soon adopted we will have more opera bouffe on the subject and the dangers to commerce will increase, while the bubonic plague will continue to reach out for more countries to conquer.

17.—See abstract in THE JOURNAL of November 9, p. 1267.

21. **Heart Suturing.**—Nietert reports a case of stab-wound of the right ventricle producing pericardial hemorrhage. The wound was sutured, the patient being conscious at the time, but he died thirty-three hours later from shock and pericarditis. The case is the first one operated on in which the pleura was not injured. Several interesting points are noted by the author. The splashing sound in the region of the heart, which he thinks is diagnostic of connection with the pleural cavity, was absent. The whistling sound showing the presence of air in the pericardium was also absent. The knife penetrated on the right side of the sternum and the wound was oblique, both of which facts are of interest. He reviews the literature at length and expresses his belief that operations on the heart for wounds will be more frequent in the future than in the past; statistics show that at least 20 per cent. of the cases can probably be saved by prompt operation.

22. **Division of the Sensory Root of the Trigeminus.**—This article is in two parts, one by Spiller and the other a report of a case with comments by Frazier. Spiller reviews the physiology of the trigeminus and the probabilities of the non-regeneration of its sensory root after its severance. His

article is elaborate and gives experiments on dogs which have been performed by Frazier, and the opinions and statements of others. From the results obtained by Bregman and from his own microscopic studies he concludes that the nerve fibers of the sensory root of the fifth nerve, both the intra- and extracerebral portions, maintain the same relative position throughout the course of the root. This is important because we may conclude that if the nerve fibers of the sensory root do not mingle freely without regard to order, the nerve fibers of the Gasserian ganglion also probably preserve a dennite order of arrangement. The nerve fibers passing distally from the ganglion separate into three distinct divisions and Tiffany's suggestion to spare the inner third of the ganglion in order to preserve vision seems, therefore, to have an anatomic basis, though it is not improbable that if this inner third of the ganglion were removed, the relief of pain would not be permanent. The practical importance, of course, of the fact whether degeneration is permanent or not rests in the modification of the operation for neuralgia by dividing the sensory root instead of extirpation of the whole ganglion which is a much more serious procedure. Spiller thinks it possible that the sensory nerve roots in man do not regenerate, and even with partial regeneration of these roots it does not follow that pain would return, and in view of this possibility, the division of the sensory root for tic douloureux is a justifiable procedure. Experiments on dogs have shown that the motor root can be spared, and if this can be done in man to any considerable extent the relief of pain may be possible without paralysis of the muscles of mastication. In the second part of the article Frazier gives details of the operation which was suggested to him by Spiller, and reports a case. His conclusions are summed up as follows: As a substitute for all operations which depend for their success upon removal of all or a part of the ganglion, he recommends an operation which depends for its success solely upon the division of the sensory root of the ganglion. Granting it will effect a radical and permanent cure, the advantages of this operation are the following: 1. It should be attended with a lower mortality. 2. It obviates a number of difficulties. 3. Its execution is, comparatively speaking, simple. 4. It is practically complete when the posterior aspect of the ganglion and its sensory root have been exposed; that is, it is practically complete before the difficulties most serious and troublesome common to other operations have been encountered. 5. The integrity of the cavernous sinus is never in danger. 6. The risk of injuring the sixth nerve is avoided. The patient, in whom both portions of the root were severed, has been greatly relieved, complete anesthesia existing over large portions of the face and scalp.

24. **Splanchnoptosis.**—Robinson finishes his article in this issue, giving a résumé of the subject in detail for which the reader is referred to the original.

25. **Appendicitis and Infectious Disease.**—Finney and Hamburger report several cases of appendicitis associated with arthritis, and maintain that for purposes of treatment appendicitis is rightly regarded as a local disease subject to serious accident readily explained by anatomic and bacteriologic factors. There seems to be an intimate relation between polyarthritis and appendicitis and he uses the analogy of the tonsil and the appendix as an argument.

26. **Chancre of the Tonsil.**—The following are the conclusions of Rhodes' article: 1. Chancre of the tonsil is often unrecognized because hypertrophy and inflammation are so frequent and are so closely simulated by the early symptoms, which often differ little from an ordinary sore throat. 2. An enlarged and indurated tonsil with a superficial ulcer upon its surface, accompanied by enlargement and induration of the contiguous submaxillary gland and which is unchanged by a prolonged course of treatment, renders a diagnosis of chancre probable. 3. The character of the chancre depends upon the original condition of the tonsil as to size, density, the amount of follicular inflammation and the coincidence of a mixed infection. 4. A certain diagnosis can not usually be made until the general eruption of the disease. 5. The explosion of the disease is no more severe than in chancre elsewhere. 6. The disease is contracted by direct contact or by various media, carrying the virus. 7. When we consider the frightful contagiousness of syphilis and the frequency with which it is conveyed to innocent persons, the most careful use of throat and nose, dental and other surgical instruments, clinical thermometers, etc., is necessary. 8. Separate instruments should be used for examination and treatment of known syphilitics, but the possibility of contamination before the existence of the lues has been recognized make it imperative that every operator should employ a rapid and efficient disinfection or sterilization of instruments after the examination or treatment of every patient. 9. Most careful instructions should be given patients as to the necessity of efficient isolation, the methods of infection, and the period of danger, and the use of individual household and other utensils should be enjoined.

27. **Instrumental Perforation of the Uterus.**—The form of accidental perforation discussed is that occurring during operative procedure by the physician. Abnormal condition of the uterine muscle may be a cause, and any attempt to explore or curette the puerperal uterus must be made with unusual care. Failure to recognize its position is also a matter of danger, and no man should attempt intra-uterine manipulation unless he is sure of the uterine position and the presence or absence of disease of the appendages. Perforation may occur because of the proximity of the menstrual period when the uterus is much congested and softened, as this may contribute to the possibility. Results of such injury may be infection from unclean instruments, hemorrhage more or less extensive, visceral injury or introduction of toxic matter into the peritoneal cavity when chemical antiseptics are employed. Whenever there is the possibility of uterine injury, irrigation should not be practiced or at least only saline solution should be used. Pelvic peritonitis may occur, but not under ordinary conditions if the technique of the operator has been perfect. The diagnosis is usually easily made. When such aseptic perforation has occurred no operative interference is required, unless there are visceral complications, when celiotomy should be immediately performed. He reports a case of uterine perforation with omental injury and a considerable portion of the omentum following the instrument down to the external os.

29. **Appendicitis in the Female.**—Downes reports 10 cases of operations on women, in some of which a diagnosis of appendicitis was made and not found, and in others where appendicitis existed and was not diagnosed. He calls attention to the necessity of bi-manual examination as a necessary preliminary step in the conduct of the case with symptoms of appendicitis. He also urges incision through the right rectus muscle. It is more often indicated than at present used by surgeons.

42. **Umbilical Hernia.**—The difficulties of radical operation for umbilical hernia have led Delatour to modify the operation as follows: "An elliptical incision is made about the base of the tumor through the skin and subcutaneous tissues down to the sac, the sac is then freed to the ring, an incision is now made through the abdominal wall in the median line, about an inch or an inch and a half below the edge of the ring, and the peritoneum opened. The finger is then introduced and swept around the ring, within the abdomen, to be sure that there are no adhesions and then with a pair of scissors the incision is carried on either side of the fibrous ring to a point in the median line an inch or so above the upper limit of the ring. This removes the sac with its fibrous neck or rings, and its contents, unopened. We have now to deal with these; the ring of hardened tissue forming the neck of the sac may now be incised so as to allow the examination of its contents. The omentum should be separated as far as possible and then ligatured and cut away; the intestine is to be treated according to its condition, if healthy, returned, and if gangrenous, resected, an anastomosis made and the bowel then returned. The closure of the abdominal wall is also important and should be done as follows: First the peritoneum and the posterior sheath of the rectus should be sewn with a continuous catgut suture,

next the edges of the rectus, which were exposed when removing the sac, and its anterior sheath should be united with chromicized catgut and the skin edges by a subcuticular suture of silk." He claims the following advantages for this method: 1. The saving of time in the handling of tissues. 2. Taking away from the abdominal cavity the contents of the sac until they have been inspected so that gangrenous intestine or omentum is not necessarily handled. If the intestine is gangrenous it can be resected without being withdrawn from the sac. The same is true of the omentum. 3. It gives a firm closure to the wound with the tissues approximated in proper layers. He has successfully performed the operation, including a resection of eighteen inches of the intestine.

43. **The Ovarian Plexus.**—From clinical and historical studies Chapman and Foote conclude that the ovarian plexus, which is homologous to the spermatic plexus of the male, is the controlling nerve supply to the ovaries, tubes and uterus, instead of the cervical ganglion of Frankenhauser.

46. **Gonorrhea.**—Wolbarst concludes that early and active treatment is indicated in every case of acute urethritis, especially before the posterior urethra has become involved. The earlier the treatment the less the chance of this occurrence. 2. A narrow caliber of the meatus strongly points to probability of posterior involvement and a severe course of the disease. Early meatotomy may be advisable. The Thompson two-glass test is liable to serious error, and needs corroborative evidence. The typical clinical picture presented by the patient in the acute stage is thoroughly diagnostic, and the presence of gonococci corroborative. For posterior urethritis the irrigation treatment is both rational and effective. With proper technique and gentleness there is a minimum of pain and danger. It is not essential that potassium permanganate be employed; normal salt solution, weak silver nitrate or copper sulphate solution have given equally good results, especially when used alternately. The heat of the fluid and the thorough mechanical flushing of the urethral canal are probably the most effective forces in bringing about the favorable results of this method of treatment. In anterior urethritis protargol in one-half to 1 per cent. solution constitutes the most valuable remedy. It is easily borne, and is not irritant nor painful. It may be safely used from the very beginning of an attack, except in those few cases where the syringe itself is not tolerated. The profuse purulent discharge usually disappears within seven to ten days, after which a muco-purulent or watery discharge may be milked from the urethra, which totally disappears after two to four weeks. The gonococci disappear after two to sixteen days, but may reappear if the protargol solution is stopped before the end of the third week. The posterior urethra is not likely to be attacked if the treatment is begun early enough and properly carried on. The average duration of the anterior cases, including the obstinate ones, is six weeks, though this period is materially shortened in private practice where the solution is employed three times daily. There is little or no pain or discomfort throughout the entire course. The advantages of the method over the older ones are: absence of pain and discomfort; brief duration of the profuse discharge; comparatively shorter duration of the disease; diminished danger of complications; early disappearance of the gonococci. The disadvantages are that the early cessation of discharges induces the patients to suspend treatment before they are entirely cured, thus bringing about recurrence, and the absence of pain and discomfort minimizes the importance of the disease in the eyes of the patient. If the solution be too strong there is a possibility of causing posterior involvement with liability to the usual complications. This is the only real danger in the use of the remedy.

47. **Phototherapy.**—Ravogli reviews Finsen's experience and briefly states some of his own. He obtained a direct result in a case of tubercular ulcer and also has had good results in other cases of lupus erythematosus and enlarged tubercular glands.

57. **Spasmodic Torticollis.**—After noticing first the symptoms, clinical history, etiology, pathology, prognosis and treatment, Hamann gives his own operative experience with neurectomy, excising the posterior divisions of the three upper cervical nerves, also cutting the muscles. He insists on the etiologic importance of frequently repeated muscular contractions in the production of disease, the uselessness of non-surgical measures, at least in advanced cases, the safety of the operation, the absence of impairment of motion after it, and the good chance of cure or improvement. He urges the performance of radical and extensive operations—excision of the nerves and divisions of the muscles.

58. **Strangulated Hernia.**—The dangers of strangulated hernia are noted and the fact is mentioned that when the case goes to operation, especially in cases of resection, there is danger of failure of anastomosis besides the danger of shock and sepsis. No case whether reduced by taxis or operation is safe until we are sure of the return of bowel function. The causes of death are principally as follows: without operation, shock; with or without operation, general peritonitis by continuity from the infected sac and hernia; from leakage of feces, sloughing of the intestines, paresis without sloughing of the portion returned resulting in ileus, septic peritonitis, general septicemia and sometimes fatal hemorrhages; asphyxia in portions of the intestines at a distance from the hernia with necrotic ulcers; also causing systemic infection, ileus, etc. With operation, accidental injury to intestine; soiling of peritoneum from infection; added shock; hemorrhage; anesthesia; intestinal obstruction from post-operative adhesions; failure of anastomosis; artificial anus; operation for closure of artificial anus. Taxis should never be attempted after the first few hours, and Jones says that while it seems ridiculous to warn modern surgeons as regards the diagnosis, in his experience the majority of cases referred to him for operation had been retained for treatment until the bowel was dead, and a large minority had existed unrecognized or neglected for nearly a week.

59. **Carbolic Acid.**—Sargent describes the treatment of poisoning cases, and in conclusion says it is safe to say that alcohol is the most perfect, the most certain, and the most handy antidote to carbolic acid which we possess.

64.—This article has appeared elsewhere. See THE JOURNAL of December 14, ¶18, p. 1635.

66. **Prostatectomy.**—MacLaren criticises the operations of vasectomy and castration as regards their utility in prostatic hypertrophy and thinks that enthusiasm over the operations has led to over-sanguine reports. The method which he considers the best consists in making a wide transverse opening, dissecting the rectum loose from the posterior surface of the prostate, exposing the bulb, then the prostatic urethra, and later, after separating the fibers of the levator ani where it merges into the capsule of the prostate, gives a clear field and makes it possible to remove many of the prostatic enlargements causing obstruction. A longitudinal opening into the prostatic urethra makes it possible to determine whether the growth has all been removed and often assists in removal, and through this opening drainage helps to complete the cure by curing the cystitis which so frequently complicates the distressing cases. He has had good results with suprapubic prostatectomy, but finds it usually necessary to make perineal section to more perfectly drain the tract from which the prostatic tumor has been removed and therefore suggests the wisdom of making the perineal section first and perhaps avoiding the risk of suprapubic opening.

69. **Rectal Prolapse.**—Halstead describes the various methods of treatment of prolapse of the rectum and after a study of the cases and a review of the literature offers the following conclusions: "1. All cases of prolapse of the mucous membrane alone can best be treated by resection of the protruding mucous membrane and suture of the cut end to the skin of the anus, as in Whitehead's operation for hemorrhoids. In mild cases, clamping and cauterizing linear folds of the prolapse are sufficient to effect a cure. 2. In recent reducible prolapse of all coats of the rectum, removal of the cause, if possible, with massage, gymnastics and appropriate internal medication, to

improve the patient's general condition should be first tried. If these fail, amputation or intra-abdominal suspension are indicated. 3. In young children, operative treatment of prolapse is seldom required. The removal of the cause, which usually can be accomplished with rest in the horizontal position, tonics and massage, will, in the great majority of cases, cure the patient. Among the most frequent pathologic conditions which bear a direct causal relation to prolapse in children are: Intestinal catarrh, rachitis, phimosis and stone in the bladder. 4. In old irreducible or in recent strangulated cases, the only treatment is amputation by the method of Mikulicz. 5. In old irreducible prolapse, or in recent cases where a fair trial of palliative remedies has been given, we have the choice of two methods—amputation or intra-abdominal fixation. At the present time no authoritative statement can be made as to the value of colopexy. It possesses the following advantages: It is not dangerous; it is easily performed, and, when it is not successful, it does not leave the patient in any worse condition than before. Inguinal colostomy should never be performed except when some special indication exists, e. g., when prolapse is associated with colitis which does not yield to treatment or when stricture or malignant diseases are present. Simple catarrhal inflammation of the prolapsed rectum does not justify opening the colon. 6. Rectopexy, if employed, should be used only in the lesser degrees of prolapse of the rectum. In invagination of the rectum and colon it is of no value. In any case its disadvantages and dangers outweigh its good points."

71.—**Creosote in Pneumonia.**—Van Zandt recommends the use of creosote for its curative effect on this disease and gives in his article a number of letters from physicians bearing testimony as to its value. His method of giving it is for the adult 7.5 to 10 grs. or minims every three hours, in urgent cases giving the dose even more frequently for a few times. He thinks that some are giving more than is necessary, and better results may perhaps be had by giving smaller doses at shorter intervals. In some cases he has had good results from 1 drop of creosote every three hours. Ordinarily he gives it without other medication. He never uses expectorants or nauseants; occasionally a few doses of some anodyne are given in painful cases and strychnia where indicated.

72.—This article has appeared elsewhere. See THE JOURNAL of November 30, ¶143, p. 1494.

73. **Fracture of the Forearm.**—The method here described by Lofton consists in approximating the ends of the bones, keeping them on the stretch and applying a two-ply one-inch adhesive plaster, twelve inches long, to the forearm, extending up the lateral aspect of the extended hand to the knuckle. The same procedure is applied to the outside and inside of the injured member. Then, beginning at the distal extremity of the metacarpal bone, he proceeds to place adhesive strips, one lapped over another, just long enough to reach two-thirds of the way around the fractured extremity, to the point of origin of the long strips. When this process has been repeated this device will have been accomplished. At times it may be necessary to throw around the strips a roller bandage two inches wide, that the plaster may more completely adjust itself. The ulna answers for the splint in the Colles and Barton fractures. No unusual deformity has resulted thus far from this treatment, but he advises scrupulous care and moderate elbow exercise daily. No interosseous union has yet been noted. The fracture plaster thus made can be worn three weeks without inconvenience and may be improved by small perforations at intervals of an inch, which will not weaken it. He likes it because it is simple and easily adjusted, because it permits of free circulation and exercise, because the patients may observe the conditions at will and because the excessive heat which accompanies bandaging is removed. It will not slip when properly applied, and may be removed when necessary by immersing in hot water for twenty minutes.

77. **Creosote in Pneumonia.**—Cummings' article was inspired by hearing Van Zandt's paper before the Central Texas Medical Association and he gives his own experiences with carbonate of creosote. He begins with 10 drops every three hours and increases the dose 5 drops daily until 20 or 25 drops are given, and in all cases uses strychnia as a stimulant, beginning with small doses in the second stage. He finds that this modifies the fever, lessens the severity of the cough and pain and otherwise seems to act beneficially. He has treated 20 cases by this method and has had no deaths.

81. **Quinin by Hypodermoclysis.**—In pernicious cases of malarial fever the administration of quinin by the mouth is often impossible on account of the constant nausea and vomiting. Gray has had good results with a method which he has not seen mentioned in the current literature on the subject, that is, a weak hot solution of one-fourth to one-half of 1 per cent. of quinin in normal salt solution by hypodermoclysis. He knows no better method of combating the tendency to circulatory stasis in these cases than by the use of large quantities of normal salt solution. The addition of a small percentage of quinin in no ways detracts from its value or adds to the irritation, so that two therapeutic indications are at once met. The solution he prefers is 30 grs. of bimuriate of quinin and iron in a pint of normal salt solution injected, with due precautions as to asepsis, into the loose subcutaneous tissue. The injection is not very painful, absorption is rapid, cinchonism prompt, and induration or local necrosis has never been produced.

FOREIGN.

L'Egypte Medicale (Alexandria), November.

Human Bites. TREKAKI.—A merchant, 54 years of age, was bitten by a young man in the left ring finger, with a loss of substance of the skin and subcutis 2 by 1.5 cm. in size. The young man had decayed teeth and a buccal abscess had been incised not long before. The bitten finger developed progressive gangrene with osteoperiostitis of the finger and lymphangitis of the entire hand. Thiriar has reported two nearly similar cases and Goebel another. Painblan described in the *Echo Méd.* of August 11, a somewhat analogous experience, two persons coming violently into collision, with a resulting injury in the forehead of one from a tooth of the other individual. Exophthalmus developed on the same side in a few days with general symptoms, coma and death. The autopsy revealed a suppurative meningitis, pyophlebitis of all the veins of the orbit and diffuse purulent infiltration of the cellular tissue in the orbit.

Annales des Mal. des Org. Gen. Urin. (Paris), November.

Acute Staphylococcus Urethritis. A. MALHERBE.—Urethritis caused by the staphylococcus albus may simulate gonorrhea, but the discharge is minimal and it is accompanied by permanent pain of a neuralgic character with cutaneous hyperesthesia of the entire genital region and even beyond. It may be as painful an affection as the most painful gonorrhea, and may last five weeks. It is not accompanied by any disturbance in the general health, and ceases spontaneously without special treatment or complications. There seems to be very little danger of infection of the wife. It is very rare in the complete form exhibited by a patient of 50, whose case Malherbe describes in detail and from which he isolated the staphylococcus. It is possible, he observes, that many cases of irritation restricted to the dilatation of the urethra in the glans, without discharge, may be of the same nature, or at least, non-gonorrheal in origin.

Bulletin de l'Academie de Medecine (Paris), November 19.

Treatment of Deafness. MARAGE.—The hearing is tested by the sounds of a "siren" reproducing the fundamental vibrations of the vowels. With normal hearing the sounds are heard at a constant distance with an atmospheric pressure of 1 mm. A tube is then introduced between the ear and the "siren." A membrane in the tube transmits all the vibrations without introducing or suppressing a harmonic. By this means the ear is massaged by the vibrations which the ear normally receives. This massage never increased the deafness nor caused pain nor buzzing in any of the tests related by Marage. On the other hand, it restored the hearing to normal in a number of cases of extreme deafness. It has proved successful in many cases

in which all other methods had failed. From his experience during the last four years, he is convinced that it is possible to arrest the progress of sclerous otitis by this means.

Improved Writing Apparatus for the Blind. Dussaud.—The apparatus devised by Dussaud enables the stamp making the letters to be applied on the same side on which they are read, which is a great improvement over the present Braille method. The apparatus is light and portable and requires only half the amount of paper.

Competition for the Audifred Prize.—This prize is an income of nearly $5000 a year, derived from an endowment, to be awarded for a cure for tuberculosis. Sixteen communications were received in competition this year. One claimed to cure tuberculosis with oxalic acid, another by a method of breathing through the nose, etc. Ten communications were from medical men, one lauded intratracheal medicinal injections, another formolized chloroform, and another dieting and fresh air. Only one of the communications was based on original experimental research. This described the author's efforts to determine whether the lesser lipase in tubercular affections was specific of the disease, and whether it could be influenced by medication or other measures in man and animals. The conclusions were negative.

Bulletin Medical (Paris), November 23.

Sacral Instead of Lumbar Puncture for Children. E. Cathelin.—When lumbar puncture is difficult for any reason such as ankylosis, exostosis, etc., or the restlessness of the subject, Cathelin recommends to puncture the lower subarachnoid cul-de-sac by way of the sacral canal according to the method which he has recently promulgated for epidural cocainization. The technique is much simpler than for lumbar puncture. The postero-superior opening of the sacral canal is higher in children than in adults and the lateral tubercles are more distinct.

Journal de Med. de Paris, November 24.

Morphin in Heart Troubles and Uremia. Lemoine.—Morphin is a stimulant for the medulla oblongata and consequently of the centers of circulation and respiration. In an affection of the aorta, morphin is the best means to combat syncope if injected at the first symptoms of distress. In infectious diseases, especially la grippe, the heart becomes irregular and weak and morphin can not be too highly recommended. The results are better than from the use of caffein or digitalis. About 3 mg. are enough, repeated three or four times during the twenty-four hours. It can be supplemented by caffein or digitalis. The former is peculiarly useful in case there are symptoms of congestion of the lungs; 20 to 50 cg. of caffein can be injected and four hours afterward 5 mg. of morphin, after which the doses can be so managed as to inject from 25 cg. to 1 gm. of caffein and 1 cg. to 1.5 cg. of morphin in the twenty-four hours. Clinical observation has shown that morphin is harmless even in uremia. It does not produce coma in this case, but merely alleviates the difficulty in breathing.

Revue de Chirurgie (Paris), November.

Survivals After Amputation of the Mamma for Malignant Tumors. Le Dentu.—During thirty years' experience LeDentu has had only 2 patients die as the result of amputation of the mamma. In 53 cases in his private practice, 26 or 49.05 per cent. are still alive after three years and 19 or 35.84 per cent. had no recurrence within at least three years. In 10 or 27.77 per cent. the recurrence was not noted until after three years. The recurrence was local in 13, local and general in 12 and general without local recurrence in 6 cases. Ten patients have survived an average of more than nine years without recurrence. He curettes the axilla in all cases and drains at this point, fastening the arm at an angle of 45 degrees to prevent cicatricial stiffness. He states that the systematic ablation of the sternal fibers of the pectoralis major and sometimes of the pectoralis minor, offers no inconvenience and ensures better results.

Gastro-Enterostomy. F. Terrier.—One death in 15 cases of gastro-enterostomy is Terrier's record. In 7, the operation was performed on account of carcinoma and the survival was four to eleven months, although several of the patients were in advanced stages of cachexia. In the others it was performed on account of gastralgia with hyperchlorhydria, simple dilatation or simple dilatation with pain or hyperchlorhydria, twice for ulcer, once for gastro-succorrhea and once for alcoholic gastritis. In the latter case the patient died from an old heart trouble. Monprofit proclaims that chronic affections of the stomach all indicate surgical intervention. There is no such thing as effective medical treatment. Pantaleoni is an advocate of the Y-gastro-enterostomy for all affections of the stomach not exclusively dependent upon the nervous system. The symptoms attributed to the circulus vitiosus after gastro-enterostomy are often merely the result of slight adhesions between some of the loops of the intestine and the abdominal wall.

Contra-Indications for the Sound in Prostatism. Lavaux.—Several years of observation of subjects with hypertrophied prostate has convinced Lavaux that the sound should never be used when the bladder can be emptied spontaneously or when incomplete retention of urine is not accompanied by insufficiency of the bladder contraction. In case of cystitis with incomplete retention, the bladder should be injected and irrigated without the use of the sound. These rules apply particularly to prostatic patients with peculiarly impressionable nervous systems, hyperesthesia of the mucosa of the lower urinary passages and to workingmen. Incomplete retention, he asserts, has no injurious influence on the upper urinary passages so long as there is no insufficiency of the bladder muscle.

Treatment of Diabetic Gangrene. Cazin.—The diabetic soil is exceptionally propitious for the development of microbian cultures, but the diabetes alone does not produce gangrene. Cazin thinks that an aseptic wound in a diabetic ought to heal the same as in a healthy individual, and consequently he amputates in case of gangrene, and without sacrificing more of the tissues than would be necessary in a non-diabetic patient. He performed last April the Lisfranc disarticulation on a diabetic, 63 years of age, inclined to atheroma. There was no pulsation in the tibialis posticus, but it was perceptible in the popliteal artery. The patient walks well on his half foot and shows no signs of recurrence. Not a drop of blood issued from the plantar flap during the operation. Tedenat has also reported a number of cases in which the external flap did not bleed during amputations in persons with and without diabetes, but results have all been highly satisfactory. Guinard does not have much confidence in a flap that does not bleed, and in such cases he removes the clots obstructing the artery. By this "catheterization of the artery" applied to the femoral in a recent case, the blood flowed freely after removal of the large clots obstructing the lumen.

Rupture of the Uterus. H. Varnier.—With one exception, every case of rupture of the uterus, 11 in number, which Varnier had occasion to observe before 1897, proved rapidly fatal, whether the rupture was complete or incomplete, spontaneous or traumatic. The treatment had been extraction of the fetus by the natural route, etc. Since that date he has operated through the abdomen in every case; 6 patients died before the operation was scarcely begun; in 6 others the operation was successful and 3 of the patients were restored to health. He and Pinard insist on the gravity of every rupture of the uterus, the impossibility of treating it properly by way of the vagina, and consequently, the urgent necessity of laparotomy at the slightest suspicion of rupture after the lesion has been confirmed by manual exploration. Total hysterectomy is not necessary; the ablation by a transverse section of the ruptured portion, leaving the usually intact cervix, is sufficient. It is wise to close the peritoneum above the stump and to suture the latter to the lower angle of the wound, with gauze drainage.

Presse Medicale (Paris), November 13.

Improved Spinal Cocainization. GUINARD.—THE JOURNAL has mentioned Guinard's success in spinal cocainization with the cocain dissolved in the patient's own cerebrospinal fluid. He is convinced that the water is the cause of the symptoms sometimes observed after this method of analgesia, and substitutes the cerebrospinal fluid. He now reports seventy cases thus cocainized without a single post-cocainic accident, headache, vomiting, agitation or anything of the kind.

Semaine Medicale (Paris), November 20.

Diagnosis and Treatment of Tubercular Pleurisy. DIEULAFOY.—Of all the methods for diagnosing the tuberculous nature of an acute serofibrinous pleurisy, Dieulafoy considers cytodiagnosis the most reliable. The fluid in acute pleurisy in a vigorous and otherwise healthy person, is undoubtedly tubercular if it contains numerous lymphocytes with red corpuscles and no patches of endothelium. The cytoscopic examination of the pleuritic fluid is at least as important as bacteriologic investigation of the sputa in pulmonary tuberculosis. The fluid in tuberculous pleurisy has a marked tendency to collect again after evacuation, and the danger from an effusion is not the amount of dyspnea it causes, but the quantity of the fluid. It may collect insidiously, without pain or dyspnea, and yet attain such quantities that the patient dies suddenly at a time when it is supposed that all danger is past and that he is on the road to rapid recovery. When the tuberculous nature of the pleurisy is recognized, the patient should be examined every day even after the acute phase seems to have terminated. The amount of accumulated fluid should be estimated from day to day and evacuated whenever necessary. After recovery the patient should be regarded as predisposed to tuberculosis, and appropriate hygienic measures should be impressed upon him, avoiding overstrain and fatigue, and seeking a higher altitude and open-air life if possible, with cod-liver oil or fat foods, etc. Dieulafoy orders before meals thirty drops of a mixture of equal parts of kola, coca and quinquina in a glass of water or wine. He also injects sodium cacodylate in 5 cg. daily doses for fifteen days each month for several months. The patient should not consider himself safe from tuberculosis until several years have passed.

Radical Treatment of Hernia Without Opening the Peritoneum. POULLET.—The incision in the skin need not be longer than 5 cm. The edges are retracted as far as possible and the hernial sac is reduced without opening it. A wire is then passed through the neck of the sac and back and forth through the lips of the wound, and fastened. This holds the sac against the abdominal wall and has proved a most effective method of treating hernia in 400 cases in Poullet's experience during the last ten years. The patient can get up and urinate at once after the simple operation, and is dismissed cured after four or five days of comparative rest in an easy chair. One of his patients was 84 years old.

November 27.

Prevention and Treatment of Whooping Cough. WEILL and PEHU.—Very careful study of 104 cases of whooping cough has demonstrated that the contagious period was during the bronchial stage, before the appearance of the characteristic spasmodic cough. After this cough appears, the possibility of contagion rapidly diminishes until by the eighth day there is no longer danger of infecting others. Attempts to isolate the specific germ have proved contradictory because after the spasmodic cough appeared, the germs soon disappeared, as evidenced by the lack of contagion. They should be sought in the throats of the brothers and sisters of the whooping child, who are still in the exclusively bronchial phase. In treatment, the necessity of avoiding every strain on the nervous system renders local applications, etc., more injurious than beneficial. Quinin has a favorable action, and is best given in a rectal suppository in these cases. Bromoform is too toxic for general administration. Weill has found the best treatment to be antipyrin by the mouth and inhalation of the fumes of quinolein. Ten to twenty drops of quinolein are added to 100 c.c. of water for each child, and boiled in a room in which the children assemble for twenty minutes three or four times a day. The quinolein disinfects the air passages and prevents bronchial infection. It has an unmistakable effect in reducing the number and the violence of the coughing spasms, as has been established by several years of experience in the Lyons hospitals.

Centralblatt f. Chirurgie (Leipsic), November 30.

Surgical Treatment of Affections of the Lungs. QUINCKE.—Suppurative processes in the lungs are the ones that require surgical intervention, and among them, parenchymatous suppuration indicates it more frequently than bronchiectasia. Quincke distinguishes five classes, acute or chronic, simple or putrid abscesses, those due to foreign bodies and tuberculosis. In the upper lobes, expectoration of the discharge is easier, but cicatrization more difficult. In the lower lobe expectoration is difficult, but conditions are more favorable for contraction of the lung tissue. Even in cases of multiple small cavities and rigid lung tissue, preventing healing, the conditions can be mitigated by an opening outward. Elastic fibers in the sputa speak for the presence of an abscess, as does also the overwhelming predominance of a single coccus, whether the strepto-, staphylo- or pneumococcus; also cases in which the purulent discharge occurs periodically. The classic symptoms of a cavity are often missing, especially when it is situated in the upper lobe. The acute, simple abscess most frequently occurs after croupous pneumonia. If it does not heal spontaneously in three to ten weeks, it should be operated. In case of a putrid focus, the indications for an operation are more urgent on account of the liability of complications. A fresh gangrenous focus without demarcation should be operated. The prognosis is good in case of an acute abscess, less favorable if putrid. Chronic abscesses heal with greater difficulty. They require removal of the wall of the thorax, besides the incision. The entire part of the lung disseminated with cavities may require resection. An abscess caused by a foreign body is nearly always putrid. Even if an exact local diagnosis is impossible, Quincke recommends to make a bronchial fistula beneath the angle of the right scapula to divert the putrid secretions and prevent secondary foci. If a severe affection is restricted to the upper lobe, the attempt to immobilize this portion of the lung by a thoracoplastic operation is well justified.

Centralblatt f. d. Grenzgeb. (Jena), November 26.

Operative Treatment of Pulmonary Tuberculosis. A. BERLINER.—Thirty-two communications have been published since 1895 in regard to operative treatment of tubercular cavities of the lungs. Eleven cases were operated on and followed for several months or years. The cavity was in the front of the right lung in Bier's patient, and the improvement that followed pneumotomy terminated in death the tenth month. Franke's experience was the same in every respect, but the survival was eighteen months. In Krecker's patient the cavity was in the lower portion of the right lung, and he died from hemoptysis. In Kurz's patient, the cavity was upper, left, and healed after pneumotomy. The patient died three years later from generalized tuberculosis. Mosler's case, front, left; cavity healed; death one year later from generalized tuberculosis. Neve's case, upper, right; general improvement. Quincke's, upper, right; death after two years from general tuberculosis. Sarfert's, upper, right; death in five months. Sonnenburg's, front, left; improvement; survival for seven years. Spengler's front, left; recovery after a thoracoplastic operation. Turban's, upper, left; in good health two and one-half years after a similar intervention. All the patients are dead except 3. These results are so far from encouraging that Koerte insists that cavities containing bacteria must be excluded from the operation. Quincke demonstrated that a tubercular cavity had no chance to heal whether operated or not, without extensive resection of the ribs over it, which favors the retrogressive processes. Spengler and Turban followed his advice and their results seem to indicate that this is the right way. The technique of

the operation is of much less importance than the selection of the cases. The general health must be fair; degeneration of the heart or kidneys and hectic fever absolutely contra-indicate it. The immediate improvement after the operation was most striking in many cases—the diminished expectoration and fall of the fever. The cavity, if opened, is loosely tamponed with gauze but drains can not be inserted on account of the danger of after hemorrhage from injury of the vessels. If the operated side does not contract as rapidly as anticipated, the process can be hastened by elastic compression, protecting the other lung with a sheet of zinc. Turban's patient was a young man with the entire left lung involved in the tubercular process. He states that surgical intervention is permissible even in such an advanced case if several months of observation have established good resisting powers, a rigid thorax and the unilateral character of the process. The general conclusions of this review of Tuffier's collected 27 cases with only one survival—Sonnenburg's patient—and Koehler's statistics of 25 pneumotomies with 13 speedy deaths, etc., are that in the restricted field of promoting the contraction and healing of the focus by the extensive removal of the ribs over it, surgery has a small but very promising sphere. The patients after any operation on the lungs should be granted the benefits of outdoor life in fourteen days at least.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., December 5 to 11, 1901, inclusive:

Bailey K. Ashford, lieutenant and asst.-surgeon, U. S. A., from duty at Fort Slocum, N. Y., to post duty at Ponce, P. R.

James L. Bevans, lieutenant and asst.-surgeon, U. S. A., recently appointed, to proceed from Decatur, Ill., to Havana, Cuba.

William Donovan, contract surgeon, from duty at Madison Barracks, N. Y., to his home in New York City, for annulment of contract.

Herbert Gunn, captain and asst.-surgeon, Vols., recently appointed and now in San Francisco, Cal., to report to the commanding general, Department of California for transportation to Manila, P. I.

Henry S. T. Harris, major and surgeon, U. S. A., having reported his arrival in New York City, is relieved from further duty in the Division of the Philippines, and assigned to Fort Slocum, N. Y.

Valery Havard, lieut.-col., deputy surgeon-general, from duty as chief surgeon, Department of Cuba, to Fort Monroe, for post duty.

Arthur C. Heffenger, contract surgeon, now at Portsmouth, N. H., to duty at Fort Constitution, N. H., Dec. 7.

Bower E. Himes, contract surgeon, from Fort Keogh, Mont., to duty at Fort Thomas, Ky.

Paul C. Hutton, lieutenant and asst.-surgeon, U. S. A., from Fort Thomas, Ky., to duty at Fort Keogh, Mont.

Dryden H. Lamb, contract surgeon, now in Washington, D. C., to proceed to his home in Owosso, Mich., for annulment of contract.

James V. May, contract surgeon, leave of absence for twenty days granted on the expiration of which he will proceed from Philadelphia, Pa., to Madison Barracks, N. Y., for duty at that post.

James H. McCall, captain and asst.-surgeon, Vols., having tendered his resignation is honorably discharged from the service of the United States to take effect Dec. 31, 1901.

Thomas U. Raymond, captain and asst.-surgeon, U. S. A., is honorably discharged as major and surgeon, Vols., only, to take effect Dec. 31, 1901.

Eugene L. Swift, major and surgeon, U. S. A., retired from active service by reason of disability incident to the service to date from Dec. 9, 1901.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended December 14:

Asst.-Surgeon J. B. Buchanan, ordered to the *Columbia*.

Surgeon N. H. Drake, ordered to the *Philadelphia*.

Pharmacist J. Cowan, detached from the Boston Navy Yard, ordered home to wait orders.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Dec. 12, 1901:

Surgeon S. D. Brooks, granted leave of absence for one day, December 25.

Surgeon J. H. White, granted leave of absence for sixteen days from December 9.

Surgeon P. M. Carrington, four days' leave of absence from Dec. 9, 1901, under paragraph 179 of the regulations.

Surgeon W. P. McIntosh, to proceed to Athens and Ducktown, Tenn., for special temporary duty.

P. A. Surgeon M. J. Rosenau, to proceed to Mexico, Mexico, for special temporary duty.

P. A. Surgeon, H. W. Wickes, to proceed to Buffalo, N. Y., for special temporary duty, assuming command of station during absence on leave of Surgeon Eugene Wasdin.

Asst.-Surgeon R. H. von Ezdorf, department letter granting Asst.-Surgeon von Ezdorf leave of absence for two months and fourteen days, cancelled.

Asst.-Surgeon M. H. Foster, detailed as inspector of unserviceable property at the port of Port Townsend, Wash.

Asst.-Surgeon L. D. Fricks, to proceed to Chicago, Ill., and report to the medical officer in command for duty and assignment to quarters.

Asst.-Surgeon W. C. Hobdy, granted leave of absence for seven days from December 15.

Asst.-Surgeon J. S. Boggess, granted ten days' extension of leave of absence.

A. A. Surgeon P. N. Barnesby granted leave of absence for fourteen days from November 9.

A. A. Surgeon R. de Socarres, granted leave of absence for one month from December 8.

A. A. Surgeon John Frick, granted leave of absence for one month from January 1, 1902.

A. A. Surgeon W. C. Mason, granted leave of absence for eight days from November 17.

Hospital Steward Henry Gahn, department letter granting Hospital Steward Gahn leave of absence for twenty days from November 11, amended so that said leave shall be from November 18.

Hospital Steward M. R. Mason, granted leave of absence for fifteen days.

Hospital Steward L. C. Spangler, granted leave of absence for fifteen days from December 14.

BOARD CONVENED.

Board convened to meet at Washington, D. C., Dec. 13, 1901, for the purpose of appointing a medical survey officer of the U. S. Coast and Geodetic Survey. Detail for the Board: Surgeon G. T. Vaughan, Chairman; Asst.-Surgeon B. S. Warren, Recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Dec. 13, 1901:

SMALLPOX—UNITED STATES.

California: Los Angeles, Dec. 3, 1 case.

Illinois: Chicago, Nov. 30-Dec. 7, 2 cases; Peoria, Nov. 1-30, 41 cases.

Indiana: Evansville, Nov. 23-Dec. 7, 5 cases.

Iowa: Ottumwa, Nov. 2-Dec. 9, 63 cases.

Kansas: Wichita, Nov. 30-Dec. 7, 4 cases.

Louisiana: New Orleans, Nov. 30-Dec. 7, 3 cases.

Massachusetts: Boston, Nov. 30- Dec. 7, 59 cases, 14 deaths; Brockton, Nov. 30-Dec. 7, 2 cases; Cambridge, Nov. 30-Dec. 7, 5 cases, 1 death; Chelsea, Nov. 30-Dec. 7, 2 cases; Gloucester, Nov. 30-Dec. 7, 1 case; New Bedford, Nov. 30-Dec. 7, 2 cases; Somerville, Nov. 23-30, 2 cases.

Michigan: Grand Rapids, Nov. 16-30, 3 cases.

Minnesota: Nov. 30-Dec. 7, Minneapolis, 1 case; Winona, 1 case.

Nebraska: Omaha, Nov. 30-Dec. 7, 14 cases.

New Jersey: Nov. 30-Dec. 7, Camden, 6 cases; Newark, 14 cases, 7 deaths.

New York: Buffalo, Nov. 23-Dec. 4, 39 cases; New York, Nov. 30-Dec. 7, 17 cases, 2 deaths.

Ohio: Cincinnati, Nov. 30-Dec. 7, 6 cases.

Pennsylvania: Lebanon, Dec. 2-9, 3 cases; Norristown, Nov. 23-Dec. 7, 11 cases; Philadelphia, Nov. 23-Dec. 7, 185 cases, 22 deaths.

Tennessee: Memphis, Nov. 30-Dec. 7, 2 cases.

Texas: San Antonio, Nov. 1-30, 3 cases.

Vermont: Burlington, Nov. 30-Dec. 7, 3 cases.

Washington: Tacoma, Nov. 19-26, 4 cases.

Wisconsin: Green Bay, Dec. 1-8, 9 cases.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Nov. 16-23, 7 cases.

Brazil: Rio de Janeiro, Oct. 20-Nov. 3, 153 deaths.

Canada: Winnipeg, Man., Nov. 16-23, 5 cases; St. Johns, N. B., Nov. 30-Dec. 7, 17 cases, 2 deaths; Halifax, N. S., Nov. 30-Dec. 7, 8 cases; Windsor, N. S., Nov. 30-Dec. 7, 1 case; Quebec, Que., Nov. 30-Dec. 7, 30 cases.

Colombia: Cartagena, Nov. 18-24, 5 cases; Panama, Nov. 23-Dec. 2, 100 cases.

France: Paris, Nov. 16-23, 9 cases, 9 deaths.

Great Britain: Glasgow, Nov. 22-29, 1 case; London, Nov. 9-23, 764 cases, 44 deaths.

Cuba: Havana, Dec. 4, 1 case from S. S. *Alfonso XIII.*

India: Bombay, Nov. 5-12, 1 death; Calcutta, Nov. 2-9, 2 deaths; Madras, Nov. 2-9, 2 cases.

Italy: Naples, Nov. 16-23, 25 cases, 6 deaths.

Russia: Moscow, Nov. 9-16, 6 cases; St. Petersburg, Nov. 9-16, 6 cases, 1 death; Odessa, Nov. 16-23, 5 cases, 1 death; Warsaw, Nov. 9-30, 3 cases.

Spain: Barcelona, Nov. 16-30, 5 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Oct. 20-Nov. 10, 3 deaths.

Cuba: Havana, Nov. 20-Dec. 3, 1 case from Br. S. S. *Ardanmohr*; 1 death from Sp. S. S. *Buenos Ayres*.

Mexico: Merida, Nov. 9-16, 3 deaths; Vera Cruz, Nov. 23-Dec. 1, 20 cases, 8 deaths.

CHOLERA.

India: Bombay, Nov. 5-12, 3 deaths; Calcutta, Nov. 2-9, 35 deaths; Madras, Nov. 2-9, 18 deaths.

Japan: Yokohama, Nov. 2-9, 1 death.

PLAGUE—FOREIGN AND INSULAR.

Hawaiian Islands: Honolulu, Nov. 27-Dec. 10, 2cases, 1 death.

Philippine Islands: Manila, Oct. 12, 1 case.

Brazil: Rio de Janeiro, Oct. 20-Nov. 3, 42 deaths.

India: Bombay, Nov. 5-12, 189 deaths; Calcutta, Nov. 2-9, 14 deaths.

GENERAL INDEX.

Use of the index will be facilitated by bearing in mind that subjects are frequently given under two or more headings, e. g., brain, cerebral, tumors, etc.; heart and cardiac; cirrhosis, liver and hepatic; child, children and infant; gland, thyroid, etc. Often, too, writers treat of the eye, ear, nose and throat under one head, etc., and the titles do not always permit of indexing under the several headings. The "General Index" contains only titles of articles, editorials, society reports, abstracts, and miscellaneous matter appearing in The Journal; the book notices, deaths, societies, marriages, authors, and titles of articles mentioned in the "Current Medical Literature" department are indexed and arranged under their separate headings instead of in the body of the "General Index."

Abdomen, contusions of, 1424

Discretion as to allowances for care of sick, 280
Dislocation, surgeon prevented from reducing, 1417
Dying declaration, what it is admissible to show, 344
Eddyites, mental soundness of, 1631
Employes, medical attendance for, 1698
Examination by expert oculist and aurist, requiring of, 794
Expert evidence, restriction of, in will cases urged, 597
Failure to make physician witness, 60
$15,000 for death of physician, 999
Flesh injury to foot, $2000 for, 1344
Free treatment, cannot bind state by promise of, 1072
Gestation, period of, 1060
Health officers, bases of recovery for services as, 657
Hip injury, $15,000 for, 1344
Imbecility, admissibility of non-expert opinion as to, 999
Improper treatment, aggravation of injury by, 1417
Injuries, $15,000 too much for, 597
  showing extent of, by movement of arm, 597
  to child, $20,000 for, 344
Injury case, admissible evidence of physician in, 1557
  permanent, physician's evidence of, 1557
  proof of, records, as to continuing, 530
  proof of, to "reasonable certainty," 936
Insanity as defense to crime, 1698
Kleptomania, opinions of experts, 1344
Knee, $300 for injury to, 1487
Leg, $8000 for loss of, below knee, 1344
Legs, $1500 for loss of, 529
  $1000 for breaking of, 716
Liability for neglect of patient during vacation, 405
  of married women for doctor's bills, 467
  of physician in local option territory, 1630
Libelous and not privileged communications, 344
License a "right," validity of act as to revoking, 657
Local option territory, liability of physician in, 1630
Malpractice case, requirements of, 530
  liability for negligence in amputation, 1487
  litigation, court terminates lengthy, 936
  sufficient evidence of, to go to jury, 61
Marriage to syphilitic, grounds for annulment of, 936
Medical book, reputation for skill as abortionist, 658
  examination, occurrences at, as evidence, 999
  examiner a general agent—fraud of, 1487
  examiner, and statements as to health, 1073
  examiner's knowledge—serious illness, 404
  preparations, right to make and use, 280
  services, data required to recover for, 716
  treatment, not required to refund cost of, 861
Mental injury from wilful wrong, 861
  suffering only, changes about allowing for, 468
Misrepresentation in procuring license, evidence of, 139
Operation, right of recovery for, 1072
Paid medical expert testimony of, 861
Passed suffering, statement of injured persons as to, 716
Personal injury case, particulars required in, 1204
Pesthouse, liability for injury of property by, 716
Physicians' claim, nature and limitations of, 1417
Poison case, attending physician as witness in, 794
Police power to regulate practice of medicine, 344
Postmortem examinations, fixing of compensation for, 1344
Powder marks and medical jurisprudence, 1000
Pregnant passenger, liability for injury to, 1487
Private examination by selected physician may be ordered, 467
Provision of law as to examination upheld, 1417
Quarantine power not authority to buy vaccine matter, 280
Rape case, no physician in attendance at trial of, 1204
Responsibility for crime, test of, 1698
Right to have hand examined by physician, 1487
Sanity, non-expert witness in inquiries as to, 860
School trustees must enforce board of health orders, 467
"Serious illness" in contract of life insurance, 999
Skill required: consultation: diagnosis: harshness, 1061
Skull and photograph admissible in evidence, 936
Smallpox suspects, city not liable for detention of, 1698
Specialist allowed his bill for "first" treatment, 1538
State board of health, disciplinary power of, 597
Summoning of surgeon by conductor of wrecking crew, 999
Survivorship, opinion evidence on, 1631
Temporary indigestion and informal consultation, 1204
Things patient may rely on—conflicting evidence, 1557
Twenty-five thousand dollars too large an award, 716
Unborn child, no damages recoverable for injuries to, 860
Validity of law requiring so much fat in cream sold, 139
Wife as witness to contract, physician calling, 1061
Woman's life, pecuniary value of, 597
X-ray photographs—notice of taking, 1631

THERAPEUTICS.

Abortion, 1557
Absorption of drugs by the bladder, 657
Acne in young, 794
rosacea, 596
vulgaris, 714
Agalactia, 1557
Albuminuria, acute, after scarlet fever, 1486
Alcohol and tobacco habits, prescriptions for, 1271
Alcoholism, 999
Alkaline douches, hot, in inflammatory diseases of uterus, 216
Alopecia areata, 1630
Amyl nitrite in seasickness, 140
Anemia, secondary, 793
Anesthesia, local, in the ear, 998
Angina pectoris, glonoin in, 59
Antipyrin in chorea, 1697
Antisepsis in gastro-intestinal disturbances, 215
Appendicitis, 528, 715, 1137
Asphyxia by drowning, 60
Aspirin as substitute for salicylates, 595
Breasts, diseased, proper method of bandaging, 935
during pregnancy and lactation, 859
Bronchitis, 1059, 1060
Bubo, 528
Burns, 215, 596, 793
Calcium chlorid for menorrhagia, 1137
Calomel as purgative, best way of prescribing, 529
Camphor in treatment of varicose ulcers, 715
treatment of ulcers with, 1138
Cancer of larynx, palliative treatment of, 793
Carbolic acid in treatment of eczema, 596
Carcinoma of skin, 60
Catarrhal conditions of female genital tract, 1137
Chalazion, 793
Chancre, simple, 1630
Chilblains, 1697
Children, arthritic eczema in, 1698
Chloretone in pertussis, 595
in surgery, 1416
Chordee, 528
Chorea, antipyrin in, 1697
sodium cacodylate in, 999
Cocain in treatment of pain in gastric ulcer, 998
Colchicum, comparative value of the seed and root of, 793
Compresses, alcohol, in appendicitis, 715
Constipation, 279, 794
Cornea, dionin in diseases of, 59
Corns, salve to remove, 714
Coryza, acute, 715
Cough in tuberculosis, prescription for, 528
Cystitis, 715
Dandruff, 794
Dental caries, 1556
Dentifrice, astringent, 1344
Diarrhea in children, 140
in typhoid, prescription to check, 1272
obstinate, of tuberculosis, prescription for, 715
of typhoid, 404
summer, of children, 216
Diabetes, 1416
Dionin in diseases of cornea, 59
Diphtheria, convalescent stage of, 1557
Drowning, asphyxia by, 60
Dysentery, sulphur in, 794
Dysentery, 215, 1271
Ear, furuncle in, 998
local anesthesia in, 998
Eczema, 215, 466, 715, 1486
arthritic, in children, 1698
carbolic acid in treatment of, 596
Empyema, 934
Epistaxis in old people, treatment of, 597
Ergot after labor, use of, 999
Erysipelas, 656
Female genital tract, catarrhal conditions of, 1137
Fissure of nipples, 794
Freckles, 60
Frost bite, 1697
Furuncle in Ear, 998
Galactorrhea, 860
Gastralgia, 1416
Gastric fermentation, 466, 998
Gastritis, acute, prescription for vomiting of, 794
Gastritis, menthol in, 998
Gastro-intestinal disturbances of infancy, 343
Glaucoma, 140, 1416
Glonoin in angina pectoris, 59
Goiter, 466, 1630
Gonorrhea, 1137
Gout, 59
Hair, prescription to prevent shedding of, 596
Hay fever, 278, 466
Hay fever, trichloracetic acid in, 596
Heart disease, 60
Hemorrhage, 1556
Hemorrhoids and ulcers of rectum, 794
Hemorrhoids, 279, 466, 1272
treated by zinc chlorid, 1486
Hepatic disorders, functional, 1344
Hepatitis, malarial, 998
Hernia, umbilical, 657
Herpes zoster, 1272
Hot fomentations, method of applying, 1272
Hyperchlorhydria, 793
Hysteria, prescription for insomnia of, 794
Idiosyncrasies toward drugs, 1629
Inebriety, outside of hospitals, 528
Influenza, 1557
Insomnia of hysteria, 794
Iritis, specific, 1137
Jaundice, catarrhal, 1343
Labor, use of ergot after, 999
Lanugo and hairs, 656
Leg ulcers, 596
Lentigo, 60
Locomotor ataxia, 935
Mania, acute, 1343
Mastitis, 860
Medicines administered combined and individually, 1697
Meningitis, 716
tubercular, sedative in, 656
Menorrhagia, calcium chlorid for, 1137
Menthol in gastritis, 998
Methylene blue in smallpox, 1416
Milk, deficiency of, 1557
Mosquito bites, 140
Mucous patches, specific, 279
Mustard in pneumonia, 794
Nephritis, scarlatinal, 715
Neuralgia, 1343
Neurasthenia, 529, 1137
Night sweats in tuberculosis, 1698
Odynophagia, orthoform to mitigate, 1630
Orthoform to mitigate odynophagia, 1630
Otitis media, suppurative, 140
Otorrhea, 1630
Paraldehyde and trional as hypnotic, 1138
Paralysis agitans, exercise in, 596
agitans, 715
Paroxysms in pertussis, 596
Pelletierin tannate in tapeworm, 657
Peritonitis, tuberculous, 715
Pertussis, 595, 596, 656, 1272, 1697
Petroleum, acute articular rheumatism treated by massage with, 1487
Pharynx, specific ulceration of, 528
Pityriasis of face and eyebrows, 935
Pleurisy, purulent, 934
Pneumonia, croupous, 998
mustard in, 794, 935, 1203
Pregnancy, hyperemesis of, 59
Prescription writing, 1343, 1415, 1485, 1556, 1629
Prickly heat, 279
Prostatitis, chronic, local treatment of, 998
Pruritus ani, 596
Pruritus, 935, 998
pudendi, diabetic, 1137
vulvæ, 935
Psoriasis, 999
Puerperal eclampsia, 59
Rectum, hemorrhoids and ulcers of, 794
Rheumatism, 595, 999, 1487
Rhinitis, acute, 1486
Rhus toxicodendron poison, 596
Salivation following ether narcosis, 657
Salol in smallpox, 1416
Santonin in tabetic pains, 140
Scarlatina, graver forms of, 1556
Scarlet fever, throat in, 1272
Sciatica, 60
Seasickness, amyl nitrite in, 140
Smallpox, 1416
Sodium bicarbonate in vomiting of pregnancy, 140
cacodylate in chorea, 998
formate in pneumonia, 935
Sore throat, 1272
Spartein, proper method of using, 998
Stomach, ulcer of, 466
Stricture, 1630
Sulphur in dysentery, 794
Synovitis, rheumatic, 935
Tabes dorsalis, 657
Tabetic pains, santonin in, 140
Tannin and bromin in pruritus, 998
Tapeworm, 139, 529
Tenia solium, 139
Tetanus, carbolic acid in, 1343
Throat, in scarlet fever, 1272
Thrush complicating dentition, 467
Tic douloureux, 1343
Tinea tonsurans, 596
Tobacco and alcohol habits, 1271
Tonic and elliminant in infectious diseases of children, 59
Tonsillitis, 1630
Toothache, 467
Toxemia of pregnancy, 999
Tracheo-bronchitis in children, 1486
Trichloracetic acid in hay fever, 596
Trional and paraldehyde as hypnotic, 1138
Tuberculosis, intestinal, in infants, 657
cough and pain in, 1137
night sweats in, 1698
Typhoid in children, treatment of, 466
Typhoid, 403, 1272
Ulcer, gastric, cocain in, 998
gastric, 216, 466
varicose, 596, 935
Ulceration, specific, of pharynx, 528
Ulcers treated with camphor, 715, 1138
Umbilical cord, 140
Uterus, inflammatory diseases of, hot alkaline douches in, 216
Vaginal diseases, 1344
Vomiting of pregnancy, sodium bicarbonate in, 140
Warts, 60, 1416
Whitlows, 934
Zinc chlorid, in hemorrhoids, 1486
Zona, 1272

AMERICAN MEDICAL LITERATURE

INDEX OF TITLES

Explanation: This index covers titles and subjects of original articles published in the medical journals of the United States and Canada during the past six months. The titles, and the journals in which they appeared, were published weekly in the Current Medical Literature department, to which references are made. The figures in ( ) refer to the paragraph; the number following, to the page in The Journal. For instance, "Abdomen, gunshot wounds of, (119) 1274" refers to page 1274 of The Journal, on which is found opposite paragraph 119, the title of paper and name of author, viz., "Gunshot Wounds of the Abdomen. E. F. Robinson." This title is listed under the journal in which the article appeared: "Kansas City Medical Record, October." Titles of articles which appeared in The Journal are indicated by an asterisk (*) before the page number.

Abdomen, contusions of, (87) 1419
gunshot wounds of, (119) 1274
pendulous, operation for relief of, (126) 1206
Abdominal and pelvic pathology, nerve reflexes due to, (145) 1063
cases, report of, (128) 142
cavity, bile in, (9) 598
cavity, foreign bodies accidently left in, (130) 1206, (55) 1488
disease, right-side, cases of, (21) 141
incisions, on making and closing, (162) 1206
operations, drainage after, *20
operations, pus in, (38) 598
operations, technic of aseptic, (67) 937
section, hernia ten years after, (129) 1062
sections in general practice, (47) 62
sections, urinary analysis in, (138) 1206
surgery, some thoughts on, (109) 1206
viscera, demonstration of model of, (58) 406
Abortion as a disease and a crime, (117) 1419
criminal, (121) 1001
infection as etiologic factor in, (80) 1062
management of, (94) 1632
resulting in acute septicemia, (129) 1001
streptococci infection complicating, (127) 599
treatment of, (45) 598, (60) 1139
tubal, (76) 141
uterine hemorrhage following, (131) 1001
Abscess, appendicular, (22) 217
brain, cases of, (70) 1345
cerebellar, (61) 469
cerebral, (8) 468
congenital, of internal genitals, (29) 937
dissecting, of abdominal wall, producing deformity, *1458
epityphlitic, observations in, (99) 406
in posterior mediastinum in connection with Pott's disease, (15) 1631
intra-peritoneal, of abdomen, (179) 863, (161) 1140
of ethmoid and antrum of Highmore, (63) 62
of kidney, case of, (89) 1062
of larynx, (173) 1275
of liver, (129) 1206
of lung, pneumotomy for, (27) 345
pelvic, (153) 63
pulmonary, surgery of, (25) 1418, (6, 72) 1488, (26) 1558
retro-peritoneal, operative management of, (98) 406
subphrenic, (86) 599
tubo-ovarian, (51) 468, (82) 717
Abscesses, pelvic, appendiceal, infrapubic opening of, (86) 1139
Abscesses, purulent and fecal, (37) 1205
retropharyngeal, after otitis media purulenta, (66) 1345
Abstinence, total, medical profession and, (92) 862
Accidents, scientific study of, (52) 1699
A. C. E. mixture and ethyl bromid in operations for adenoid vegetations, (2) 1345
Acetanilid, considerations concerning toxicity of, (124) 142
Acetone, bearing of alimentation on excretion of, (126) 346
Acid, carbolic, (59) 1727
carbolic, poisoning, (117) 1062
intoxication, (66) 1559
intoxication of diabetes, (99) 1274
Acne vulgaris, (153) 346
Acromegalia, (32) 141, (156) 470, (142) 938
Acromegaly, unusual features in, *887
Actinomycosis in man, (137) 142, (13) 658, (38) 1558
Actinotherapy in cutaneous medicine, *21, (15) 217
Acute diseases, nervous complications in, (161) 938
Addison's disease, (92) 1001
disease treated with suprarenal extract, (37) 141
disease, tuberculosis and, (14) 1345
Address, Albany College of Pharmacy, (78) 1632
Albany Hospital Training School for Nurses, (53) 1000
Albany Medical College, (37) 1345
American Dermatological Association, (122) 406
American Medical Association, (135) 599, *1431
American Medico-Psychological Association, (97) 718
American Neurological Association, (62) 345
Arkansas Medical Society, (74) 218
Association of Medical Officers of Army and Navy of Confederacy, (137) 282
Berks County Medical Society, (114) 599, (74) 862
British Medical Association, (68) 1274
Canadian Medical Association, (111) 1062, (82) 1139
Eastern Ohio Medical Association, (88) 1632
Executive Health Officer's Association of Ontario, (112) 1062, (126) 1346
Illinois State Medical Society, (103) 141
In medicine, (93) 1139
John A. Creighton Medical College, (92) 406
Kentucky School of Medicine, (39) 1000
Kentucky State Medical Society, (52) 281, (50) 717
Maritime Medical Association, (64) 717
Medical Society of Virginia, (46) 1559
Address, Medico-Chirurgical College, (120) 1346
Nashville Academy of Medicine, (102) 531
National Fraternal Congress, (67) 1062
Nebraska State Medical Society, (61) 141
New Hampshire Medical Society, (69) 717
North Missouri Medical Association, (73) 717
Ohio Medical University, (87, 88) 281
on Surgery, (152) 1206, (29) 1345
Ontario Medical Association, (126) 406, (112) 531
Pennsylvania State Medical Society, (24) 1138, (46) 1345
Philadelphia County Medical Society, (47, 48) 1345
San Joaquin Medical Association, (92) 1632
Sioux Valley Medical Association, (38) 1061
Southern Illinois Medical Association, (142) 142
Southern Surgical and Gynecological Association, (44) 1699

of forearm, treatment of, (73) 1727
of jaw, intradental splint for, (79) 938
of neck of femur, treatment of, (56) 218
of skull, (61) 862
of skull, compound comminuted depressed, (5) 1699
simple, of vault, with meningitis, 834

Fractures, ambulatory treatment of, (61) 281, (51) 659
ambulatory treatment of, involving hip-joint, (151) 142
compound, of extremities, suggestions for treatment of, (54) 345
general considerations of, (58) 281
femur and humerus, (104) 718
of femur, treatment of, with ambulatory pneumatic splint, *1605
of humerus, suggestions bearing on, (57) 1062
of neck, anatomical treatment of, *1661
of nose, (140) 63
of shaft of femur, treatment of, (166) 1275
of skull, observations on, (133) 1206
ununited, (101) 1062
French Congress of Surgery and Urinology, (37) 1727
Frenum, intermaxillary, means of reducing overgrowth of, (59) 1000, (35) 1061
Frost-bite of cornea, (31) 1632
Fuller, Samuel, pilgrim, doctor and deacon, *1298
Funeral delayed in Philippines, (96) 346
Fusel-oil poisoning with reference to copper-reducing substances in urine, (19) 530

Gall bladder, architecture of, (121) 63
bladder, surgical malposition of, (60) 1488
duct, hydraulic pressure to open common, (125) 1062
Gallstone, a large, *265
in common duct, (107) 1559
unusual case of, (190) 142
Gallstones, (49, 50) 62, (94) 346
cholecystectomy for, (32) 1632
cholecystitis and cholangitis as complication of, *1453
clinical history and diagnosis of, (164) 863
diagnosis of, (146) 1001, (1) 1631
duodenal stenosis due to, (144) 863
etiology of, (163) 863
fat necrosis in connection with, *1176
when to operate upon, (8) 795
Galvanism for uterine hemorrhage, (121) 1559
Ganglion cells, studies in morphology of, in rabbit, (98) 1274
resection of superior sympathetic cervical, (16) 62, (59) 345
superior cervical sympathetic, in glaucoma, *1588
Gangrene, carbolic acid, (119) 218, (33) 1488
case of multiple, *445
emphysematous, caused by aerogenes capsulatus, (7) 405
in newborn, (45) 1727
of bowel wall, (37) 1205
senile, case of, *1319
symmetrical, (145) 142
Gas and gas cysts of central nervous system, origin of, (104) 862
Gasserian ganglion, examination of, by Nissl's method, (98) 862
ganglion in cadaver, removal of, (28) 217
Gastrectomy, partial, for hemorrhagic ulcer, (22) 1138
Gastric secretions in chronic rheumatism and rheumatoid arthritis, (33) 468
surgery, (73) 1488
ulcer, indications for operation in, (15) 717
ulcer, surgical aspect of, (76) 659
Gastritis, chronic, (138) 599
complicated with myasthenia gastrica, (22) 598
menthol in treatment of, (129) 863
Gastro-enteric infection in infants, treatment of, (38) 468
Gastroenterostomy, (153) 938
and intestinal resection, (83) 1489
death after, (39) 141
indications for, (94) 1419
vicious circle after, (18) 468, (21) 530
Gastro-intestinal tract, experimental surgery of, (46) 1699
Gastro-jejunostomy in gastrectasis, (31) 717
Gastrostomy, (71) 62
operation, modified, (134) 1139
Gelatin in hemorrhage, (47) 717
Genital organs, tuberculosis of female, (78) 1205
Genito-urinary diseases, symposium on, (165) 863
organs, briefs on surgery of, (155) 63, (125) 938
surgery, anesthesia in, (62) 281
Genuvalgum, (100) 531
German measles, lamellar desquamation in epidemic of, (96) 938
surgical clinics, impressions of, (128) 1274
Germany, no thieves in, (62) 659
Gestation, ectopic, (87) 346, (74) 531, (64) 1205, (39) 1757
triple ectopic, (105) 1700
ruptured ectopic, successfully operated on (53) 1345, (137) 1633
Giacomini, Carlo, central fissure of, (31) 658
Gingivitis, simple, etiology and treatment of, *161
Girl, American, health of, (139) 1489
Girlhood, gynecological and obstetrical significance of, *174
Girls, measurements of, in private schools, (5) 468
Glanders, diagnosis of, by Strauss method, (67) 1559
Glandular fever, (138) 1346
Glaucoma, removal of superior cervical sympathetic ganglion for, (59) 345
subacute, resection of ganglia for, (144) 1275
superior cervical sympathetic ganglion in, *1588
Glioma of the brain, (61) 1139
of retina, (65) 281, (84) 938, (74) 1700
Gluten and diabetic foods of commerce, (32) 1138
Glycerinated lymph, experiences with, (19) 1558
Glycosuria, transient or simple, (69) 218
Goiter, complicated by stenosis of trachea, (70) 62
pathology of, (79) 1700
Gonococcus and its toxin, (17) 1000
Gonorrhea, (76) 598, (37) 1488, (50) 1699
acute, (11) 1488
acute, modern treatment of, (75) 218
acute, protargol in, (46) 1727
acute, report of special committee on, (113) 938
as social problem, (139) 346
chronic, (76) 218
chronic, and post-gonorrheal urethritis, (23) 141
chronic, dilating irrigations in treatment of, (62) 1139
comparative treatment of, (61) 659
etiologic factors in, (165) 863
in boys, *827
in women, (166) 863
is it local or constitutional affection? (82) 599
local treatment of, (31) 937
sequelæ of, (169) 863
special committee of American Medical Association regarding, (137) 1206
therapeutics, capital sin of modern, (39) 717
treatment of, (25) 345, (136) 407
urethritis or, (122) 1139
what are the consequences of, (103) 406
Gonorrheics, plea for, (126) 163
Good of the order, for the, (30) 1062
Gout and obesity, respiratory conditions dependent upon, (32) 1273
and rheumatism, (96) 1559
irregular, and hepatic inadequacy, (142) 469
prevalence and treatment of, (176) 1275
Government duty, a (149) 1701
Granular lids, (24) 1488
Graves' disease, consideration of, (122) 863
Greek terms, on onomatology in regard to, (85) 1001
Growing pains, (40) 468
Growths, intrathoracic new, (59) 1488
Guaiacol treatment of tuberculosis, (128) 1700
Gude's pepto-mangan, clinical report on, (95) 1559
Guinea-worm disease, (3) 1273
Gumma of ciliary body, (66) 1700
Gunshot wound of kidney and stomach, (20) 1138
wound of right lung with complications, (98) 1062

Hemiplegia, (42) 1699
massage in, (14) 1726
Hemoglobinuria, malarial, (142) 1419, (78) 1727
Hemoglobinuric fever, cases of, (153) 1140
Hemolymph glands, contribution to histology and pathology of, (95) 862
glands, human, normal histology of, (134) 1700
Hemolysis, (6) 468, (33) 531
Hemophilia, antenatal treatment of, *503
neonatorum, (82) 218, (63) 598
Hemorrhage and sepsis following nasal operation in a "bleeder," (146) 470
cerebral, symptomatology of, *908
concealed accidental, (124) 1206
dangerous, after removal of enlarged tonsils and adenoids, *911
fatal, from varix of pampiniform plexus, *199
from a pyothorax, (121) 282
gelatin in, (47) 717
into orbit of newborn, (149) 1275
lencocyte counts in, *501
meningeal, (80) 1489
mononephrous, nephrectomy for, (24) 1699
nasal, treatment of, (76) 1700
of retina, (89) 938
post-abortion, (72) 281
post-operative, *16
postpartum, (132) 599, (127) 1489
prevention of, in ophthalmic operations, by use of adrenalin chlorid, (116) 1206
secondary, two cases of, (99) 531
uterine, (83) 1632
uterine, adrenalin in, (125) 1560
uterine, following abortion, (131) 1001
uterine, galvanism for, (121) 1559
uterine, stypticin in, (76) 346
Hemorrhages, pulmonary, influence of Colorado climate on, (9) 1138
Hemorrhagic diseases of newborn, (65) 598
Hemorrhoidal circulation, study of, (23) 598
clamp, new, (21) 62, (1) 1000
Hemorrhoids, (125) 599, (24) 795, (126) 1139, (42) 1418, (140) 1419, (43) 1632

Hemorrhoids, internal, treated without general anesthesia, (52) 1274
operation for radical treatment of, *1658
Hemostasis, electro-thermic, in abdominal pelvic surgery, *419
Hennepin County Medical Society, early days of, (48) 1000
Hepatic cirrhosis, (59) 469
Hepatopexy, (36) 1061, (140) 1275
Hepatotomy, special treatment of biliary calculi with special reference to, *1573
Heredity, (35) 405
and acquired characteristics as social question, (143) 1489
and acquired characters, (129) 1633, (72) 1727
and epilepsy, (111) 282
and tuberculosis, (18) 1138
as factor in life insurance, (71) 1062
as social question, (143) 1489
in mental disease, (26) 1345
study in, (141) 863
Hernia, autoplastic suture in, *1162
complicated by hydrocele, (132) 28
complications of injection treatment of, (132) 1275
diaphragmatic, (80) 1489, (19) 1632
early infantile, inguinal, of vermiform appendix, (114) 1274
epigastrica, (14) 1631
epigastrica and fatty tumors in epigastrium, (31) 1699
incarcerated, intestinal obstructions caused by, (53) 1274
inguinal, in children, radical cure of, (37) 1418
inguinal, operations for, (52) 1632
inguinal, surgical treatment of, (38) 1000
inguinal, worsted truss in, (131) 1206
left cecal, (61) 218
of urinary bladder, (9) 62
permanency of cure in radical operations for, (2) 1631
radical cure of femoral and inguinal, (53) 218
reduced "en bloc," (36) 1138
strangulated, (164) 938, (11) 1061
strangulated, causes of death in, (58) 1727
strangulated, in infants, (17) 1138
strangulated inguinal, (104) 718
strangulated, of bladder, (23) 658
strangulated umbilical, (65) 1274
ten years after abdominal section, (129) 1062
treatment of, (72) 717, (31) 795
umbilical, (62) 1559
umbilical, adhesive plaster, strapping in, (26) 405
umbilical, new procedure for, (42) 1727
ventral, (49) 281
Heroin, (109) 406
hydrochlorid, action of, (42) 62
indications and contra-indications of, (36) 1488
therapeutics of, (101) 1419

in surgical sense, (47) 1418, (21) 1488
intra-uterine, best treated by intra-irrigation, (50) 1000
Infection, malarial, treatment of, (41) 1274
spread by domestic pets, (2) 598
streptococcal, complicating abortion, (127) 599
streptococcal, following labor, *619
through food, (97) 469
Infections, acute and chronic, mast-cells in, *1596
of soft tissues of female pelvis, (81) 1700
septic, of kidney and cystonephroses, (65) 141
streptothrical, (68) 598
surgical, and cystic enlargements of kidney, (63, 64) 141
Infectious diseases, *97
Inflammation, acute lacunar, of tonsils, (62) 1000
acute mastoid, operative treatment of, (17) 217, (60) 1000
chronic purulent, of middle ear, treatment of, (53) 1559
of ear, (35) 862
of mouth, neurotic, (83) 62
of posterior part of eye, new operative procedure for treating, (12) 937
pseudomembranous, of mucous membrane, (53) 862
role of endothelium in, *1521
treatment of, (110) 1139
uric acid, of middle ear, *514
Inflammations, catarrhal, of upper respiratory tract, (120) 218
Inflammatory affections of nails, (54) 1418
exudates, non-surgical treatment of, (116) 218
Influenza, (139) 142
as causal factor in acute mastoiditis, (70) 1139
aural complications of, (49) 1345
cardiac lesions of, (59) 937
epidemic, (79) 717
ocular complications of, (102) 218
psychoses of, (57, 58) 937
pulmonary form of, (101) 218
sunshine and, (28) 1418
Infrapubic opening of pelvic appendiceal abscesses, (86) 1139
Infusion, intravenous saline, (154) 1275
Inguinal canal, new method of operating on, (84) 531
Injuries, feigned and real, *1295
of extremities, conservative treatment of, (137) 63
Injury to eye from explosion of water glass, (148) 1206
Insane, another plan of state care of, (81) 938
Corning's anesthesia among, (176) 863
diathesis, heredity and transmission of, (107) 1001
Indiana laws for commitment of, (77) 599
jury trials of, (150) 63
limitations of surgical work for, (9) 468
needless public expense in care of, (70) 1727
physician's duties in committing to hospital, (110) 282, (113) 1419
systematized history of, (117) 1489
women physicians in care of state, (93) 1062
Insanities, acute, treatment of, (133) 532, (76) 717
of adolescence, (55) 659
Insanity, acute, treatment of, in general hospitals, (20) 598
598
and criminal cases, (42) 1274
cases of, (124) 1062
circular, clinical researches in, 106) 218
clinical classification of, (104) 938
early symptoms indicating, (13) 217
evidences of, (88) 1139
home treatment of, (105) 1489
importance and difficulties of correct diagnosis in, (33) 141
impoverished blood and, (123) 1559
prevention of, (110) 1274
puerperal, (29) 62, (94) 1274, (137) 1275
prophylaxis of, (113) 282
relation of pelvic diseases to, (43) 345

Insanity, should determination of, in law differ from that in medicine, (151) 1275
Insolation complicated by lobar pneumonia, (98) 1001
Insomnia, treatment of, (77) 62
Inspection of schools, daily medical, (17) 1488
Institutionalism, (97, 101, 103) 1206
Instruments, sterilization and care of, (88) 469
Internal lesions, nature of, in deaths from superficial burns, (19) 1418
medicine in nineteenth century, (94) 282, (136) 599
International Congress of Nurses, report of, (45) 1632
Intercocular base line, measurement of, (82) 938
Intestinal antiseptics, (130) 938
diseases of children, (133, 137) 1139
obstruction, acute, (39) 1632
obstruction, clinical aspect of, (4) 717
obstruction, chronic, (74) 1139
obstruction diagnosed by *x*-rays, (19) 1000
obstruction, diagnosis and treatment of, (51) 141
obstruction, due to adhesions, (26) 141
obstruction, due to constricting bands, (38) 1138
obstruction due to Meckel's diverticulum, (123) 1274
obstruction following abdominal section, (138) 863
obstruction from surgical standpoint, (72) 1632
obstructions caused by incarcerated hernia, (53) 1274
perforation, surgical intervention for, in typhoid, (... 863
perforations, (33) 1345
surgery, knot within the lumen in, *952
tract, experimental surgery of, (45) 1699
tract, treatment of some chronic conditions of, (149) 1063
Intestine, primary resection of, in gangrenous hernia, (2) 405
searcher, perforated, (156) 1206
traumatic rupture of, (11) 345
Intestines, pistol-shot perforation of, (173) 863
Intoxications, classification of, from pathologic standpoint, (5) 405
Intracranial pressure after head injuries, (26) 530
Intra-irrigation in intrauterine infection, (137) 1346
Intranasal operations, technique of, (71) 1345
Intratracheal injections in bronchial and pulmonary affections, (9) 1000
Intra-uterine amputations, *547
Intubation of larynx, (133) 1275
report of an, (130) 218
Intussusception, case of, (39) 62, (37) 1138
during first year of infancy, (127) 863
Iodids and mercury in syphilis, comparative value of, (133) 282
Iowa State Association of Railroad Surgeons, (98) 141
Volunteer Infantry, medical history of 49th, (122) 1559
Iridectomy, extraction of cataract without, *1513
Irido-chloroiditis, double suppurative, in association with purpura hemorrhagica, (90) 469
Iris, rupture of, from contusion of eyeball, (116) 406
total retroflexion of, *1289
Islands of Langerhans of pancreas in diabetes, degeneration of, (71) 1559
Jaundice, obstructive, mortality of operation for, (63) 218
Jaw, sarcoma of, (63) 1274
traumatism, (169) 1206
Jenner, Edward, and smallpox before and after introduction of vaccination, (121) 1206
Jews, infrequency of tuberculosis among, (21) 1345
Johnson, Samuel, medical history of, (13) 717
Joint injuries, diagnostic test and constitutional treatment in, (159) 346
Jonnesco's operation, present status of, (102) 469

Katatonia, (110) 141
Kelcid. (123) 282, (113) 599
Keratosis palmaris et plantaris, (77) 531
Kidney, amyloid, anatomy of, (95) 1489
and stomach, gunshot wound of, (20) 1138
carcinoma of, unusual case of, (136) 1700
case of abscess of, (89) 1062
congenital cystic, *825
contribution to surgery of, *172
disease, ophthalmoscopic examination for, (21) 405
disease, x-ray in diagnosis of, (123) 1700
floating, in women, (1) 937
left, congenital pelvic malposition of, (22) 281
medical treatment of diseases of, (43) 937
minor surgery of, (3) 345
some surgery of, (79) 1559
wandering, (153, 160) 142, (20) 937, (110) 1001
physiology of, (80) 281
stone diagnosis and treatment, (5) 1138
subcutaneous wounds of, (40) 1699
surgical infections and cystic enlargements of, (64) 141
Kidneys, anatomy of, (54) 531
condition of, and use of diuretics, (1) 530
cystic, case of, (49) 141
during pregnancy, (124) 1700
gouty affections of, (3) 530
physiology of, (93) 1489
remarkable condition of, in eclampsia parturientium, (48) 218
stones in, (125) 1419
Kitasato, Japanese pathologist, (81) 599
Klebs-Loeffler bacillus, clinical significance of, (3) 1418
Knee-joint, monarticular inflammation of, (62) 1559
surgery of, (99) 1419
Knife, failure of, in treatment of cancer, (28) 1205
new rectal fistula, (1) 1000
Knot within the lumen in intestinal surgery, *952
Kraske operation, is it justifiable in women? (39) 598
Kraurosis vulvae, (81) 218

Labor bag, antiseptic, (119) 1206
can injuries to parturient canal be avoided during, (137) 1063
emergencies of, (101) 1489
how to conduct case of, (80) 406
in dislocation of uterus, (65) 1205
normal, how to conduct case of, (125) 1700
second stage of, conduct of, (60) 531
some emergencies of, (132) 938
sudden death after, (84) 1700
three protective points in management of, (104) 1632
Laboratory aid in surgical technique, (30) 1205
clinical, in private practice, (49) 1418
clinical, relation of, to hospital, (106) 1206
feeding with reference to modified milk fund, (45) 531
research, modifications in operative surgery from, (2) 1558
Laceration, urethral, (41) 281
Lacerations, cervical, what is significance of, (77) 141, (46) 218, (3) 1000
of pelvic floor, (99) 1700
vaginal and cervical, (136) 1346
Lachrymal gland, endothelioma of, (114) 1700
pipette, use of glass, (53) 1062
Lactic acid, new method of testing for, (31) 531
La grippe, experience with, (167) 63
in children, (80) 938
with pulmonary and cerebral complications, (163) 1206
Lamellar desquamation in epidemic of German measles, (96) 938
Lane lectures, the, (17) 861, (19) 862, (5) 937, (16) 1000, (17) 1061, (7, 27) 1138, (21, 24) 1205, (7, 21) 1273, (23, 30) 1345, (8) 1418, (15, 27) 1488
Laparotomy, (137) 1560
cases, hints in management of, (164) 1206
Laryngeal disturbances in diseases of central nervous system, (85) 62
Laryngitis, atrophic, (131) 218
edematous, cases of, *182
treatment of, *177
tuberculous treatment of, (2) 861
Laryngologic and rhinologic literature, critical and desultory remarks on, (126) 218
Laryngology and its place in medical education, (31) 1138
in medical education, (18) 1061
study of, in university and in the higher medical education, *158
Larynx, improved introducer for intubating, (120) 142
inflammatory and ulcerative, treatment of, (54) 62
intubation of, (133) 1275
stenosis of, following fractures, (118) 469
Laws for commitment of insane in Indiana, (77) 599
medical, enforcement of, depending on organized profession, *1301

Meningo-myelitis, chronic, in cocker spaniels, (69) 1559
Menopause, the, (73) 218
Menorrhagia, etiology and treatment of, (164) 347
and metrorrhagia, etiology and treatment of, (178) 142
Menstruation, age of first, in United States, (124) 1001, (67) 1274
factors modifying, (132) 63
painful, as factor in determining character of operations on uterine appendages, (67) 406
status of, (66) 406
Mental depression and malignant disease, (17) 1345
disease, dispensary treatment of, (99) 718
diseases of childhood, (14) 140
disturbances in cardiac disease, (20) 405
enfeeblement, (61) 1205
impressions as factor in treatment of disease, (66) 218
medicine, past and present, (68) 218
therapeutics, (105) 1001
therapeutics in nervous and mental diseases, (69) 598
weakness of women, physiologic, (111) 1419
Menthol in treatment of gastritis, (129) 863
Meralgia paresthetica, (50) 141
Mercury, (84) 1001
Mergler, Marie J., (101, 102) 1139
Mesentery, fibroma of, (14) 598
Metabolism in diabetic coma, (66) 1559
Meter angle, size of, (82) 938
Methylene blue, (75) 281, (91) 531
Metric system in prescription writing, (15) 1558
Metrorrhagia, etiology and treatment of, (164) 347
Michigan, medical registration in, (42) 1488
Microscope, the, (122) 218
Microscopic aids in diagnosis and treatment of pneumonia, (58) 62
Microscopy, bacteriology and chemistry in nineteenth century, (95) 282
clinical, bacteriology and chemistry in surgical practice, (137) 599
Microtome, carbon-dioxid freezing, (117) 63
Middle ear, complications of, (153) 1419
ear, membrana tympani and mastoid, uric acid inflammation of, *514
ear, treatment of chronic purulent inflammation of, (53) 1559
ear, tuberculosis of, (104) 469
Midwifery, notes on practice of, (57) 1488
Migraine, pathology and treatment of, (28) 1488
Milchzucker in der Säuglingsnährung, (163) 1275
Military surgeon, status of the, (85) 1274
Milk commission, report of work of, of New York, (6, 26, 29) 1205
modification, deductions concerning, (10) 1558
modification for infant feeding, importance of, (44) 862
undiluted, in chronic gastro-enteritis of rachitic infants, (4) 861
Mind, (156) 863
Mineral springs of California, necessity of dietetic management of, (102) 1001
Mirror-writing and inverted image, *1380
Miscarriage and abortion, management of, (94) 1632
treatment of, (59) 531
Mississippi river water, bacteriologic report on, (135) 1139
Mitral insufficiency, pregnancy complicated by, (20) 281
Mobile uteri, treatment of retroflexions of, (84) 718
Model, demonstration of, of abdominal viscera, (58) 406
Mola hydatidosa totalis, case of, (123) 346
Mongolism, case of, (44) 141
Morbus caeruleus, case resembling, (97) 531
Morphin habit as nervous disease, (98) 63
sickness, method of controlling, (125) 406
Morphinism, suggestions for lessening the frequency of relapses after treatment of, *1292
Mosquito an insignificant factor in propagation of yellow fever, (13) 468
the, (48) 1274, (122) 1419, (73) 1559
Mosquitoes and their relation to disease, (177) 863
in malaria, (127) 1001
of New Orleans, habits of, (178) 863
Motor insufficiency of stomach, (50) 659
Mountain fever, (119) 1700
Mouth and nasal cavities, prevention of infection through, (20) 141
breathing on dental arch, influence of, (7) 281
examination of, in infancy (12) 1345
Movable kidney, corset for, (67) 345
Movements, localization of, (70) 1559
Mucous patches, non-syphilitic, of throat, (63) 1000
polyp, the, (110) 1700
surfaces, diseased, ointment for, (161) 346, (79) 531
Mules' operation, *1369
Municipal control of dependent classes, (132) 1419
Murmurs, endocardial and exocardial, (70) 218
Mushroom poisoning, experience with, (41) 1559
Music, therapeutic benefit of, (115) 599
Mutes, education of, by aural exercises, (74) 1001
Myasthenia gravis, (77) 1001
Mycosis, case of, (156) 1140
of tonsil and base of tongue, (20) 1727
Myelitis, acute transverse, case of, (37) 862
Myeloma of spine, with compression of cord, (1) 1061
Myocardium, role of, in pericarditis, *1577
Myomata, uterine, how shall we deal with, *196
Myomectomies for fibroids during child-bearing period, (27) 658
Myomectomy of nine myomas, (78) 141, (149) 470
pregnancy following, (11) 598
Myometrium, the, (87) 218, (75) 659
Myopia, high, remarks on surgical treatment of, (149) 1206
Myosis and ptosis from paralysis of cervical sympathetic by gunshot wound, (101) 346
Myositis, gonorrheal, (92) 141
Myriapods, pretended expectoration of, (32) 1558
Myxedema, case of, (118) 346
Myxochondro-endothelioma cylindrimatodes, (114) 1700

Nails, treatment of diseases of, (57) 1418
Narcosis, medullary, (124) 863
medullary, lipoma removed from cheek under, (12) 217
nitrous oxid and ether, results of, (5) 1418
Narcotic drug habits, (157) 1275
Narcotics and hypnotics, use and abuse of, (128) 938
in pediatrics, (99) 1559
Nasal bones, correction of displacements of, (19) 1488
catarrh, home treatment of, (126) 1560
cavities, asymmetry of, (75) 1418

Nasal cavities, spraying and insufflating the, *113
deformities, etiology of, (65) 1000
deformity from medial furrow, (27) 405
diseases, chronic, relation of middle turbinate body to, *189
obstruction, relation of, and obscure cases of asthma, (67) 717
septum, acute edema of, *192
septum, serous extravasation cysts of both sides of, (12) 1062
sprays, use and abuse of, (166) 1206
Nasopharynx in scarlatina, treatment of, (50) 598
primary carcinoma of, *371
National Jewish Hospital for Consumptives, cases examined for, (33) 405
medical bureau, institution of, (107) 1206
Nauheim treatment, (10) 62
Nausea incident to chloroform anesthesia, method of controlling, (125) 406
Nebraska's medical pioneers, (103) 1274, (101) 1632
Neck, traumatic emphysema of, (66) 1205
tuberculosis of glands of, surgical treatment of, (59) 1062
Necrosis, extensive, of inferior maxilla, (188) 142
of cranial bones, (157) 63
of ileum, (108) 531
Necroses of liver, (117) 863
Needle for silver wire, (22) 62
holder, Knox improved Monk's, (157) 470
Negro, the future of the, (7) 795
cardiac lesion in, with reference to pericarditis, *1581
Neoplasms complicating pregnancy and labor, (62) 1418
intracranial, (4) 1488
malignant, infectious theory of, (62) 1488
malignant, of stomach, indications for operation in, (10) 795
multiple primary, (34) 1273
Neotherapeutics, pantherapist and, (27) 937
Nephrectomy, (100) 531
first, and first cholecystotomy, (160) 863
for mononephrous hemorrhage, (24) 1699
for removal of calculus of ureter, (106) 1139
Nephritides, chronic, (120) 1700
Nephritis, acute, (97) 1489
acute, symptomatology in, (52) 141
case of, (162) 938
calculous, and urethritis, indications for operation in, *1451
chronic, anatomy of, (95) 1489
chronic, fatal cases of, (9) 1489
chronic interstitial, (161) 63, (45) 717
interstitial, cardiovascular system in, (30) 1727
malarial, case of, (69) 1139
microscopic examination of urine in, (94) 1489
Nephrolithiasis, (40) 1138, (57) 1700
renal hematuria and, (122) 1700
Nephropexy, (36) 217
new principle in, (29) 1699
Nephrorrhaphy, present status of, (110) 599
with flap fixation, (11) 62
wound, advantages of closing with aseptic adhesive strips, (33) 1273
Nephrotomy with drainage, (35) 1727
Nephro-ureterectomy, technique of, (47) 218
Nerve cells, new formation of, in cerebral tumor-neuroglioma, (100) 862
reflexes due to abdominal and pelvic pathology, (145) 1063
Nervous and mental disease, limitations of surgery in, (38) 141, (157) 346
and urinary manifestations following la grippe in aged, (7) 658
children, (130) 1700
Nervous complications in acute diseases, (161) 938
diseases in children, (58) 1488
diseases, fear as element of, *1526
diseases, functional, care and treatment in convalescence from, (104) 1139
system, circulation in, (120) 1001, (151) 1419
system, importance of more general study of diseases of, (12) 468
system, proper method of teaching anatomy of, (9) 1061
system, syphilis of, *1105, (57) 1205
Neuralgia of rectum, (36) 1632
intercostal, operative treatment of, (23) 1727
phenalgin in, (51) 1000
treatment of trifacial, (33) 795
Neurasthenia, (158) 470, (11) 717, (95) 1001, (106) 1274, (5) 1488
evils arising from failure to recognize, (28) 345
hydrotherapy in, (119) 1062
psychology of, (42) 1345, (100) 1489
severe, dependent on anemia, (72) 1001, (128) 1489
sexual, (36) 281
treatment of, *1656
Neurasthenic spine, the, (3) 1631
Neuritis, alcoholic multiple, with peculiar changes in Gasserian ganglion, (27) 1345
infectious multiple, cases of, *1529
prognosis in, (70) 1700
sciatic and brachial, (100) 1419
sciatic, due to uric acid diathesis, (118) 1346
Neuroglia, studies on, (133) 1700
Neuroglioma, (91) 1206
Neurological lectures, (70) 1205
Neuro-retinitis, double, complete recovery from, *1587
Neuroses, masturbational, (37) 281
in orthopedic practice, (10) 281
rectal reflex, (123) 1489
traumatic, (15) 62, (39) 531, *1605
Neurosis, reflex, from disturbed pelvic mechanism, (126) 1489
Neurotherapeutics, pantherapist and, (154) 1701
Nevus linearis, cause of streaks in, (98) 1139
pigmentosus, multiple, case of, *553
New disease, a, (36) 1345
Newfoundland sealing fleet, trip as surgeon with, (97) 1139
New York Post-Graduate Medical School and Hospital, clinical demonstration at, (93) 531
State Association of Railway Surgeons, work done by, (165) 142
surgery, notes on, (79) 406
Night blue, flagella staining with, (68) 1559
Nitrate of silver in typhoid, (174) 142
Nitrous oxid and ether narcosis, (85) 218, (5) 1418, (90) 1419
Noma, epidemic of, (71) 1418
Non-municipal hospital, advantage of, (76) 937
Normal salt solution, (151) 63
salt solution by hypodermoclysis, (109) 1419
North Carolina Medical Society, report of chairman of Section on Obstetrics, (183) 142
Nose and ear, foreign bodies of, (10) 937
and throat, catarrhal diseases of, *243
and throat in general practice, (95) 1139
and throat work in history of medicine, (114) 469, (135) 938, (113) 1139, (80) 1345
and throat in their relation to diseases of chest, (116) 599
and throat, syphilis of, (53) 1205
and throat work for general practitioner, (156) 63, (97) 282, (106) 469, (150) 938, (90) 1346, (128) 1419
fibroma of, (84) 1418
maggots in, (148) 470
Noses and ears, artificial, (16) 1418
Nosologic study of manifestations of mania, (30) 598
Notes from my practice, (75) 1205
Nourishment by ordinary food, (122) 142
Nuclei pontis, development of, (120) 63
Nuclein bases and eosinophile leucocytes, (25) 862
Nucleus dentatus of cerebellum, model of, (127) 63
Nurse, the trained, (172) 1275
Nurses, trained in obstetric cases, (43) 1274
Nutrition and stimulation, (160) 346
diseases of, in infants, (30) 281, (59) 406

Obstetric and gynecologic practice, nature in, (42) 281
cases, facts regarding, (87) 1139
cases, trained nurse in, (43) 1274
experiences, interesting, (21) 345, (63) 531
operations and cases in University Maternity, (75) 406
operations, major, (125) 1274
patients, our duty to, (70) 1001
practice, (108) 1632
practice, colpeurynter in, (77) 1488
practice, technique in, (119) 1206
Obstetrics, (67) 531
address in, (17) 1205
anesthesia in, (60) 1205
early prophylaxis in, (50) 1559
gynecology and, progress of, (35) 1000
instrumental and operative, (62) 531, (44) 1139
practical, remarks on, (97) 599
practice of, *611, (32) 937
prophylaxis in, (91) 1062
selected topics in, (39) 1345
Obstipation, (7) 62
Obstruction, acute intestinal, (124) 1560
acute intestinal, following appendicitis, (54) 1488
intestinal, (88, 131) 1419
nasal, and ear disease, (31) 1488
prostatic, prostatectomy in, *1151
prostatic, to urination, (63) 1488
of bowel by enterolith, (56) 1274
Obstructive diseases of lower bowel, (74) 1062
Occipito-posterior positions, (1) 795, (34) 1061, (78) 1488
Occlusion, congenital, of duodenum, (59) 62
Occupation as affecting death-rate, (102) 406
Octogenarian, paraphimosis in an, (33) 1727

Scalp, treatment of ringworm of, *1389
Scarf-pin, case where, was swallowed and passed per rectum on seventh day, (104) 218
Scarlatina and measles, high temperature in, (94) 531
treatment of, (141) 1063
treatment of nasopharynx in, (50) 598
Scarlet fever, (133) 938, (131) 1560, (155) 1701
fever and measles, prevention and sequelæ of, (173) 142
fever, deafness from, (106) 1419
Schönlein's disease, (29) 1138
School girl, pubescent, (74) 141
hygiene, some suggestions regarding department of, *970
hygiene in reference to transmissible disease, (66) 598
life, some considerations regarding hygiene of early, *1025
medical inspection in Chicago, *1385
Schools, daily medical inspection of, (30) 1632, (28) 1699, (18) 1727
medical inspection of, and prevention of spread of contagious diseases, (118) 938
Scientific evidence, fallibility of, in medical jurisprudence, (147) 1489
research, *327, (2, 23) 468, (22) 530
Sclerosis, amyotrophic lateral, (12) 1699
multiple, in child, (41) 468
Scolecitis, differential diagnosis of, (65) 1632
Scurvy, infantile, (4) 1061
infantile, and marasmus, (68) 1488
infantile, with recovery, (40) 62
Sealing in North Atlantic, (128) 406
Segment, pelvic floor, of uterovarian artery, (32) 1727
Seidlitz salt in catarrh of stomach, (76) 281
Semen, biologic test for, *1721
Semilunar bone, forward dislocation of, (49) 659
Seminar method in medical teaching, *741
Senses, how the evolution of, expands the world, (127) 1139
Sensibility, muscular and cutaneous, (76) 1559
Sepsis, puerperal, (143) 346, (129) 532, (43) 717, (71) 937
puerperal, prophylaxis and treatment of, *615
Septic infection, some dangers of, from remedies and methods in common use, (46) 281
treatment, (91) 282
Septicemia, antistreptococcus serum in, (11) 1726
blood washing in, (156) 142
diagnostic value of blood examinations in, (112) 218
Septum, congenital longitudinal, of vagina forming a double vaginal orifice, (74) 346
nasal, (79) 1345
nasal, as found in skulls of mound-builders, (74) 406
operations, variation in technique of, (137) 938
Serous diseases of maxillary antrum, (115) 469
Serum-albumin, fallacy to avoid when using Heller and ferrocyanic, (98) 218
Serum therapy and immunity, (64) 1274
therapy in streptococcal infection, (66) 531
Serums, antitoxin animal extracts and, (172) 142
Sex, evolution and psychology of, (80) 1559
Sexual function in man, disorders of, (126) 938, (110) 1489
instinct and its control, (69) 659
instinct, development and control of, (100) 1632
instinct, development of, (117, 282, (110) 1419
intemperance, (11) 281
Sewage disposal or purification, (90) 282
Shock, (89) 1632
general consideration of, (66) 281
Shoulder joint, clinical notes on injuries to, (127) 142
Sick, outdoor treatment of the, (66) 717
Sigmoid and colon, inflammation of, (11) 405
Sigmoiditis, (169) 1275
Sigmoidopexy for prolapse of rectum, (164) 1275
Silver nitrate injections in phthisis, (29) 658
salts, newer, (109) 406
Sinus, frontal, anomalies of, *239
frontal, empyema of, *233
phlebitis, (70) 1418
Sinuses, accessory, of nose, importance of diseases of, (144) 346
frontal and ethmoidal, empyema of, (10) 217
nasal accessory, after treatment of operation on, (24) 405
venous, of brain, wounds of, (57) 218
Sinusitis nasi and otitis media following influenza, (89) 1419
Sklagraphic diagnosis for renal and ureteral surgery, *1228
Skin, complications of syphilis of, (31) 598
carcinoma of, *1590
covered by green scales, mildly inflammatory condition of, (139) 863
diseases, Roentgen rays in treatment of, *820
diseases, therapeutics of, (48) 1727
grafting, (138) 63
grafting by means of freezing, (17) 281
grafting in treatment of stenosis of larynx, (52) 1488
Skull, fracture of, (61) 862, (133) 1206, (93) 1346, (5) 1699
Sleep, suggestion during, (109) 218
Smaller medical colleges and medical education, (35) 1273
Smallpox, (80) 346, (57) 469, (157) 1140, *1608
and vaccination, *1677
and vaccination, recent epidemic of, (152) 1140
at Michigan Asylum for Insane, epidemic of, (8) 1726
diagnosis of, (2) 1699
diagnosis of mild and irregular, *302
distinguishing characteristics between mild, and chickenpox, *305
epidemic of, (40) 345, (58) 598, (125) 1206, (135) 1275, (93) 1419
epidemic in orphanage, (79) 1632
eruption, (22) 1558
historical note on, (18) 1558
in Minnesota, (39) 658
in private practice, notes on cases of, *912
mild, (77) 1345
modern, observations on, (57) 598
observations made in, (39) 937
old and new, *299
practical management of, (46) 937, (152) 1701
prophylaxis of, (20) 1558
pseudo or modified, *295
Smallpox, recent epidemics of, and failure of glycerinated lymph, (100) 599
recent experience with, (84) 141, (87) 406
sanitary features of, *299
types of, (138) 407
unusual type of, (6) 795
why is present epidemic likely to continue, (122) 1489
Snake bite, unusual after-effects of, (5) 861
Snakes, hallucination of, (40) 1558
Social evil, the, (41) 406
Sociologic problems in relation to marriage, (113) 218, (140) 1063
Sodium cacodylate, clinical test of, (121) 599
tungstate test for combined chlorid in chyme, (25) 598
Soft palate, papillomatous growths of, (138) 938
Somnambulism, (114) 1489
Southern California, observations on, (11) 1345
Illinois Journal and Association, (135) 63
Southwest, aid and semitropic, and tuberculosis, (106) 1489
Spasm, nodding and rotatory, of head, (52) 598
Spasms, post-delivery, (109) 282
Spasmus nutans, unusual case of, (69) 1488
Spaying of cows for more and better milk, (144) 1700
Special health commissioners, report of, (115) 1633
Spectacles and eyeglasses, making and fitting of, (139) 63

fever, mosquito insignificant in propagation of, (13) 468
fever, prevention of, (26) 1273
fever, propagation of, (7) 530
fever, transmission of, (165) 938
fever, two ways of transmission of, *1387
jessamine, tincture of, in spasms, fevers, etc., (140) 346

Zygadenus frumenth and zygadenus venosus, composition of, (70) 1559

AMERICAN MEDICAL LITERATURE

INDEX OF AUTHORS

This Index includes the names of authors of articles which have appeared in this journal, as well as of those listed under Current Medical Literature. This practically includes the names of those who have published articles in all the leading journals of the country. The * preceding the page reference indicates that the article appeared in full in THE JOURNAL.

Aaron, C. D., (16) 1061
Abbott, A. C., (62) 1345, (1) 1488
Abbott, A. W., (41) 217
Abbott, F. C., (40) 1727
Abbott, G. E., (138) 346
Abbott, L. F., (144) 1700
Abbott, L. J., (101) 1632
Abbe, R., (24) 468, (1) 1726
Abell, I., (47) 937, (118) 1419
Abrams, A., (44) 62, (55) 598, (45) 1488, (17) 1699
Abt, I. A., (40) 62, (48) 141, (65) 218, (38) 281, *445, (59) 469, (114) 1001, (80) 1489
Ackert, W. S., (24) 1273
Adaml, J. G., (5) 405
Adams, A. L., (49) 1139
Adams, F. L., (89) 1206
Adams, J. H., (117) 1489, (52) 1699, (38) 1727
Adams, W. F., (97) 1139
Adamuck, E., (118) 1700
Adler, Jr., L. H., (31) 345
Adt, L. F., (82) 1418
Ager, L. C., (6) 1138
Agramonte, A., (1) 217
Aikin, J. M., (145) 346, (36) 717, (108) 1274, (7) 1726
Albertottl, G., (108) 346
Alden, C. H., (24) 217, (13) 1418
Alderton, H. A., (30) 937
Aldrich, C. J., (91) 346, (14) 405, (35) 658, (137) 1139
Alexander, S., (40) 658, (69) 937
Alexander, W. J., (38) 217, (78) 717
Alford, E. T., *834
Alger, E. M., (153) 346, (25) 468
Allaban, J. E., (81) 1700
Alleman, L. A. W., (2) 658
Allen, C. W., (72) 1205, (6) 1418, *1593
Allen, D. P., (10) 861, (2) 937, (132) 1206
Allen, L. M., (106) 1062
Allen, M. K., (46) 937, (152) 1701
Allen, S. B., (12) 937
Allen, S. E., (66) 1001
Allen, W. L., (130) 1419
Allison, C. C., (143) 346
Allison, J. E., (52) 281
Allison, W. R., (87) 141
Allport, F., (58) 531
Allport, W. H., (64) 141
Allyn, H. B., (26) 281, (14) 468, (10) 1699
Alvord, A. W., (60) 1418
Amberg, E., (85) 141, *323
Amberg, S., (69) 1488
Ambler, C. P., (147) 1063
Amyx, R. F., (28) 217
Anders, H. S., (28) 1418
Anders, J. M., (86) 62, *77, (32) 1273
Anderson, H. B., (84) 1139
Anderson, J. C., (157) 1701
Anderson, M., *90
Anderson, W. S., (9) 1000
Andrews, A. H., (128) 218
Andrews, E. W., (71) 62
Andrews, J. W., (123) 1206
Andrews, R. R., *3
Angell, G. M., (113) 469
Anthony, H. G., *104
